" Dry-plate photography having lately been so perfected by the use of gelatine, a ready means is placed in the hands of amateurs of executing work in every respect equal, if not superior, to that obtained by wet collodion. Many who have tried dry plates, of which for some years past there has been a great variety, may be disposed to think this a somewhat overdrawn statement; but a fair trial of some of the gelatine dry plates now to be obtained leaves absolutely no longer room for doubt. This point admitted, it will be at once seen that the impediments of the wet process no longer becomes an absolute necessity, thus almost altogether reducing the labour formerly incidental to the practice of

landscape photography, which to many must have been a serious drawback.

" It is proposed to hold monthly evening meetings, when subjects interesting to those practising the art could be introduced and discussed, thus affording an excellent opportunity of improvement, which it is thought many amateurs, at present working by themselves at a great disadvantage, would be only too pleased to be able to avail themselves of. It is also proposed to hold during the summer months one or two joint excursions to places of interest, for the purposes of a field-day.

" These and many other details will, however, be matters of subsequent arrangement, to be decided by the representative council, to be elected at the preliminary meeting, which will be held at an early date should a sufficient number of amateurs respond.

" Trusting you can give the movement your earnest support, and awaiting the expression of your approbation, I remain, dear sir, yours faithfully,

ALEXANDER CONAN,

Hon. Secretary, *pro tem.*

Rosemeath, Sandymount Avenue, Dublin.

" To Amateur Photographers in Ireland."

Critical Notices.

ESTHETICS OF PHOTOGRAPHY. By WM. HEIGHWAY. (London: Piper and Carter.)

NOTWITHSTANDING the youth of photography, it possesses a somewhat extended literature devoted solely to it; but that devotion has been almost solely to the specially technical part of the new art science. Although art results constitute the essential final end of photography, the art aspects and possibilities have received but little attention comparatively. With the exception of Mr. Robinson's admirable work, "Pictorial Effect in Photography," no book until now has been written on the art side of photography. The volume before us is not unknown to our readers, since the bulk of it has already appeared in the PHOTOGRAPHIC NEWS; and, we think, all who have read the chapters as they appeared from time to time in our pages will be glad to possess them in their consecutive and connected form in a book. The circumstance to which we have referred precludes us, perhaps, from entering into any detailed criticism here. We may, however, without impropriety, say a few words about the book, which, as we have hinted, derives a new and additional value from appearing as a book, beyond what its contents possessed in separated chapters. Whilst it is essentially an instruction book, it is not only an instruction book, but a book of very interesting reading. There is no attempt to deal with art in its application to photography in a series of dry rules. The writer talks about the art possibilities of photography with a loving tenderness and intelligent appreciation which imply a complete belief in his subject. He leads the reader on until he is as much interested in the matter as the writer, and, having secured his reader's interest and confidence, he then proceeds to instruct him, and show him what may be done and how best to do it. We may add that whilst the subject is a great and an ambitious one, this is a small and modest book, and should be in the possession of every photographer as a companion to "Pictorial Effect in Photography," by Mr. Robinson, to whom this little work is dedicated in the following modest, appreciative words:—"To H. P. Robinson (Author of 'Pictorial Effect in Photography') this book is inscribed as a slight expression of admiration of his works—photographic and literary—and in acknowledgment of the author's indebtedness to him for many hints, of which he has availed himself, and embodied in this book."

THE PHOTOGRAPHIC ART OF TO-DAY. By RICHARD WALZL. (Baltimore.)

THIS interesting little brochure is practically a somewhat ambitious trade circular. It is really the address of com-

munication of a photographer to his patrons and sitters. It is made interesting by sketches, historical and critical, of photography, and it is made instructive by abundance of valuable hints to sitters, as to when to sit, how to sit, what to wear, &c. Sizes, styles, prices, &c., are fully discussed, and advice offered. Two fine illustrations are given. Altogether, this is one of the most handsome little pamphlets of the kind that we have met with.

THE PRIZE PAPER: A Weekly Magazine for the Youth of Both Sexes. (London: J. HENDERSON, Red Lion House.)

We rarely review in the pages of our essentially technical journal anything not specially addressed to photographic readers. Occasionally, however, general literature comes fittingly under our attention, because of its special excellence. The initial idea of this magazine is an excellent one. Its aim is to encourage budding talent in its readers, amongst whom it will find many of its contributors. Youthful readers are invited to send in their original efforts in writing tales, sketches, essays, and poems, and also in producing original drawings. Prizes are offered for first, second, and third degrees of excellence in different departments. In some cases kindly criticisms are given of the published contributions, showing points in which they are defective, and how they may be improved. The literary management of this novel experiment is in the hands of the conductors of the "Young Folks Budget," probably the most interesting and wholesome, the best and cheapest, of the numerous magazines for the young of the present day.

GARDENING ILLUSTRATED: A Weekly Journal for Town and Country.

A NEW, cheap, and excellent journal devoted to gardening, which, as many photographers are interested in horticultural pursuits, we recommend with confidence to our readers.

DARK-ROOM WINDOWS FOR GELATINE PLATES.

BY H. BADEN PRITCHARD, F.C.S.,

Of the General Photographic Establishment of the War Department. I HAVE recently been experimenting with ruby glass with a view to establishing a safe window for lighting the dark-room, a casement that would furnish sufficient illumination for development, while at the same time it would not fog the gelatine film. If you cannot trust your dark-room and its ordinary lighting, there is no other way for it but to stop out the light altogether until you have placed the film fairly in the developing solution, when you may let in yellow rays without risk. You must have light of some sort for proper development, however, and unless you are content with very little indeed, you run considerable danger, as everybody knows, of fogging the gelatine image.

The principal dark-room at Woolwich, being of comparatively large dimensions, has a casement as big as an ordinary house window. For general work, therefore, it is most efficiently lighted; but gelatine plates are no more to be developed therein than in the adjoining work-room. I decided, therefore, to have the window glazed with deep ruby, in the meantime making use of a dark-tent set up inside the dark-room for changing and developing gelatine plates. A sample of ruby glass was forwarded to me prior to the panes being fitted into the casement, and with this I made experiment. I chose a Dallmeyer No. 1B portrait lens for the test, placing inside the camera a Swan gelatine plate. The orifice of the lens was carefully closed by a piece of ruby, and an exposure in a good light was made. At the end of three minutes the slide was shut down and the plate developed. The result was a well-defined though faint image of a factory opposite, whose roof and chimney were very well rendered.

A second experiment was made with a similar gelatine plate, with the same lens and the same exposure, but this time with two thicknesses of ruby in front of the lens. On development, after exposure, as I have said, for three minutes in a good light, there was the same image, rather fainter, it is true, but roof and chimney as plain as ever.

These results at once brought me to a standstill, for although I had contemplated a window of double ruby, this second thickness availed nothing in the presence of such sensitive plates. Other samples of glass were obtained, but with the same result, and when the supply of samples ceased, I bethought myself of trying orange in conjunction with ruby. The plan succeeded: I found that two thicknesses of ruby and one of orange at once gave me a medium through which the light entered without any deleterious effect upon the gelatine film. A single thickness of deep ruby and one of orange was likewise, I found, capable of protecting a gelatine plate for three minutes in a camera fitted with No. 1B of Dallmeyer. So that photographers, instead of going to the expense of a double window of costly ruby, will find that if they still continue to employ their old orange casement, one thickness will answer the purpose. Indeed, as I have shown, two thicknesses of ruby is not to be depended upon alone, and I believe that if a photographer desires to have plenty of light in gelatine development, he must perforce make use of orange light and ruby light combined.

I do not suppose my remarks have anything of novelty about them, but as everybody, "more or less," is busying himself with the gelatino-bromide process, it behoves all to contribute their mite. The proper lighting of the dark room is of the first importance, for clear and brilliant negatives can only be secured by the banishment of all hurtful illumination.

Correspondence.

ILLUSTRATIONS OF WORKING CARBON.

SIR,—In speaking of the value of the illustrations to Mr. Foxlee's paper on the carbon process, it is an error that I suggested the reproductions should take the form of a "presentation print for next year." I must leave the South London Photographic Society to do as they think best, or any other way by which photographers may become possessed of these valuable illustrations.

I cannot help thinking but that if photographers could see them, and have a description with them of the conditions which can produce such results, a great impulse is likely to be given to the carbon process, and many would try to work it who do not now.—Yours respectfully,

GEORGE COLLINS.

WORKING GELATINE PLATES.

SIR,—The wide and increasing interest now felt, as shown by the correspondence in your columns, may, I trust, induce you to give me opportunity to recall to your readers a few of the considerations which tend to success in portraiture and landscape work on the new rapid gelatine plates.

I may premise by reminding those of your correspondents last week who ask Mr. Nelson to publish his process, that the fullest possible working details of gelatine plate-making have repeatedly been published. There are very excellent reasons why few succeed, as they who try will soon find out. Those of your readers who live in the country, and did not have the opportunity to hear the interesting discussions at the Photographic Society, and to see the pictures and negatives then shown, or to join in the even more pleasant informal conversation after the regular meeting was dissolved, can have little idea of the perfection to which the new process has been brought. Not only are gelatine negatives as good as collodion, but they contain that peculiar "soft vigour" and roundness

and sweetness which are only obtained from collodion at its best. But many have failed, and many more will do so, and they will always be able to blame their plates, just as aforesaid they blamed the bath.

First let me call attention to the stern and absolute necessity for ruby light. It may be said that I myself worked in orange light. True, in dull cold weather, with bleak N.E. wind; but when spring came I had fog, and gave it up. I bought my experience, and value it. The shadows of gelatine plates should be perfectly clear glass, and those parts of the plate which have been shielded by the frame should be so also; until this is the case, your light is not right unless you have an improper proportion of ammonia in the developer. The earliest experience of most experimenters is fog and flatness; many never surmount it, because they do not credit the real causes.

Gelatine plates are infinitely more sensitive than any "lightning" or other process used, and consequently over-exposure for one thing, and improper quality of light in the developing room, soon tell the mistake. Try developing a plate by an artificial light protected by ruby glass—you will then get a standard to go by. Let me, for a moment, diverge to explain the difference between developing by ferrous oxalate and alkaline pyro. The former is a very simple and convenient method, but it has the disadvantage that the preparation which is used is continually changing, and as it changes, so does the time of development vary. It is very tedious for any amount of work, but it is simple, and all should learn by trial what can be done by it.

Alkaline pyro is preferable, and is employed by a large majority. With the most perfect plates no bromide is necessary as a restrainer, and the time of exposure is consequently much shorter. If bromide, however, be thought necessary, it should be very sparingly employed on commencing development. During development a piece of card should be in the right hand, to shield the dish from direct rays from the source of light. The system of intensification afterwards with silver is one to be resorted to as rarely as possible. The worker will soon find what his negatives should look like, and act accordingly.

Failures are fewer than with wet plates, but a fresh set of precautions are necessary all round. Long washing after fixing is very undesirable; it should be rapid and effective. The use of alum to avoid frilling should not be necessary, but in certain states of the atmosphere is useful. Those who prefer to immerse in alum before fixing, or to mix alum with the hypo., are on the safe side, but it should rarely be necessary from frilling or swelling up of the films.

I have had the question put more than once, Can you obtain on gelatine plates the highest requirements of modern portraiture? I have no hesitation in replying in the affirmative.—I am, respectfully, SAMUEL FRY.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The usual monthly meeting took place on Thursday, the 8th inst., the president, Mr. CHARLES ADIN, in the chair.

The minutes of the previous meeting were read and confirmed.

The *Bulletin* of the Belgian Photographic Association was laid upon the table.

Mr. W. B. WOOD read a paper on "Collodio-Bromide Emulsions" (see page 244), and exhibited a number of very excellent prints from negatives by the same process.

The CHAIRMAN thought these photographs were about the best collodio-bromide emulsion work he had seen produced by any of the members, and a special vote of thanks was awarded to Mr. Wood for his communication.

The Honorary Secretary, (Mr. W. J. CHADWICK) exhibited a very small photometer, the invention of Mr. W. B. Woodbury,

and explained its use to the printer, and also as a guide to the exposure of negatives.

Mr. WIGGLESWORTH exhibited a small negative by the zinc bromide process, and at some length explained that the negative, like all others he had taken, was not a satisfactory colour; he wanted a warm brown colour.

The SECRETARY said he liked a greenish tinge.

Mr. WIGGLESWORTH said he liked a sort of greenish brown.

The SECRETARY exhibited three small negatives, which were exposed and developed by his younger brother, Master John A. Chadwick, a boy thirteen years old. They were on Wratten and Wainwright's ordinary gelatine plates, and were developed with pyro. These negatives were examined by the whole of the members, and pronounced very good work for one so young.

Mr. GREGORY brought forward several portraits, most of which were from gelatine dry plates, and he also explained the particular way or modification in which he had developed these excellent pictures.

Mr. GARSIDE presented some prints from the negatives taken by artificial light, a few meetings ago, and offered to supply any member of the Society with a print gratis, not as a specimen of good or excellent portraiture, but a reminiscence of the experiment.

The SECRETARY exhibited a series of six cabinet photographs (instantaneous photographs by Messrs. Wratten and Wainwright on their instantaneous plates). He (Mr. Chadwick) also exhibited a couple of pantoscopic prints which he had taken a few years ago, the same figure of a gentleman being introduced three times on the one plate. These were examined by the members with great interest, many of them never having seen or heard of such photographs before. Mr. Chadwick said that the inconvenience of wet collodion having to be used with the pantoscopic camera had in a great measure caused it to fall into disuse, but now that gelatine had made such rapid strides, the inconvenience of working with the pantoscopic camera would be considerably diminished.

The CHAIRMAN touched upon the out-door meetings, and explained that nothing had yet been decided, but that in all probability the Council would arrange for a photographic excursion as soon as the weather was favourable.

Mr. NORON expressed himself highly satisfied and delighted with the results of gelatine plates. He thought it was a "grand process," the process of the future, and proposed a wholesale vote of thanks to the gentlemen who had brought such excellent subjects of interest before the meeting.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The seventh ordinary meeting of this Society was held in 5, St. Andrew Square, on the evening of Wednesday, 7th May, JOHN LESSELS, Esq., president, in the chair.

The minutes of previous meeting having been approved, Miss Jessie Fullarton, Mr. Robert Murray, Mr. James Simpson, and Mr. William Carlile were unanimously elected ordinary members of the Society.

Mr. ROBERT BOW, C.E., F.R.S.C., then delivered a lecture on the theory of colour sensation, illustrated by diagrams and numerous interesting experiments. The lecture embraced Mr. Bow's latest researches and discoveries in relation to this subject, which, for many years past, he has made his peculiar study. He recapitulated some of the more interesting points of two lectures he gave before the Society in the year 1870, on the theories of colour sensation, and on theories of colour decoration; and gave some of the leading proofs of the correctness of the views first announced by Wollaston and Young, that the simple sensations of colour were red, green, and violet-blue. He noted that there had been some slight difference of opinion held by the followers of Wollaston—Herschel and Helmholtz naming the most refrangible colour *violet*. He adduced reasons for believing that the correct colour was between these two, viz., a violet-blue, such as given in appearance by a moderate thickness of deep-coloured solution of ammonio-sulphate of copper. His chief argument was this, that the pure colours are not seen with a highly illuminated spectrum; the colour near H, under intense illumination, becomes of a sickly, faded, pinky-purple character, and the blues and yellows are unduly developed, arising from the principle that no one colour sensation can be intensely excited without sympathetically exciting at the same time the other two, and usually one more so than the other; thus in the Wollastonian spectrum, given by the light from the sky, and a medium width

of aperture, we have red, a narrow strip of orange yellow, then the blue and violet; but as the aperture is gradually reduced, the blue becomes more violet from reduced excitement of the green-seeing nerves, while the violet becomes bluer from the reduced sympathetic excitement of the red-seeing nerves, so that eventually the colour above the green becomes uniformly violet-blue. Another original argument which Mr. Bow advanced was this: the length of the whole visible spectrum is dependent upon the degree of illumination, and becomes greatly contracted on making a great reduction in the supply of light. Now if there be truth in the theory that the colours are due to three irregularly superimposed spectra, each spectrum should undergo contraction independently when the illumination is reduced, and this is really the case; thus the lighter blue first disappears from the contraction apart of the violet-blue and green; and then, on a very great reduction of the light being made, the yellow band itself becomes dulled. He had attempted to register the centres to which these contractions tend, and gave, as rough approximations, for red, C·82 D; for green, D·80 E; and for violet-blue F·37 G, on the ordinary prismatic spectrum, corresponding with Angstrom wave-lengths of about 6,000, 5,375, and 4,610 respectively, but the last determination is not so trustworthy as those for red and green. As is well known, when the light is very greatly reduced, the red-seeing nerves, compared with the others, become much less excited, and so when the reduction of the light is made very extreme, no red is embraced in the spectrum. It may, for instance, begin at D·38 E, and rise to above F·54 G, and show a feeble green below a point about E·81 F, and a feeble violet above the same.

The PRESIDENT, in a few appropriate remarks regarding the importance of the subject selected by Mr. Bow, invited Mr. Norman Macbeth, A. R. S. A., to express his views as to the practical value of Mr. Bow's investigations.

In response, Mr. MACBETH said that this lecture by Mr. Bow was one of his happiest efforts. He did not know of any one better qualified to take up the subject, and he had looked forward to this evening with much interest, expecting to hear something of real value, an expectation which had in no sense been disappointed. He must, however, remark that, notwithstanding the theories advanced by Mr. Bow, and in spite of the conclusive experiments with which he had supported them, he was at a loss to see how he, as an artist, was to make use of them. He would like to know from Mr. Bow how it was possible for him, with ordinary pigments, to produce a yellow, if red, green, and violet were the only colours available. True, Mr. Bow had shown how this was to be done under peculiar conditions, not, as he could see, available to an artist. He owned he was greatly taken by surprise when he saw the various colours evolved from the mingling of tints which a painter would never dream of employing if he desired such results, and he desired information how he could make a practical use of the facts demonstrated.

Dr. HUNTER said he failed to understand how the combination of the three primary colours suggested by Mr. Bow could be of any practical value to the artist. If all known colours are produced by the mixing in definite proportions of these three colours, then an artist has no need of any but these three; yet the artist's colourman provides scores in every variety of tint, and the artist is glad to avail himself of them. He differed from Mr. Bow in his idea of primary colours, and held that the most enlightened decorators of all ages had employed reds, yellows, and blues as the foundations of all their colour combinations.

Dr. THOMSON said he had listened with very great pleasure to Mr. Bow, the more so as what he had heard was not a re-hash of old ideas, but the outcome of original investigations, and showed that the lecturer could speak with an authority based upon practical acquaintance with his subject. As he understood the discussion, he considered the fundamental ideas of the lecturer and the gentlemen who had just spoken were upon different bases—for whereas Mr. Macbeth and Dr. Hunter only entertained the material pigments as found in the colour-box, Mr. Bow dealt only with the pure impressions made by these colours as illustrated by his practical demonstrations.

In replying, Mr. Bow stated that the direction the discussion had taken was that he had anticipated. He found it very difficult to separate the idea of paints from colour sensations. His whole arguments were based on colour sensations, and not on pigments.

A hearty vote of thanks to Mr. Bow closed the meeting.

The first out-door meeting of the session was held on Friday, 19th May, the locality selected being Dalkeith Park, which, by the kind and special permission of His Grace the Duke of Buccleuch, was thrown open to the members of the Society. The party started from the Waverley Station per North British Railway shortly before ten o'clock; the weather being favourable, a pleasant day's outing was anticipated. Dalkeith is situated about six and a-half miles S.E. of Edinburgh, and is quite an interesting country town; the ruins of the old parish church, which stand near the centre of the town, impart an air of antiquity to it. Judging from the character of the details, this building must have been originally one of great beauty, and an imposing architectural feature in the rural landscape. On arriving at the park, the party was met by the chief keeper, Mr. Chewler, who had been instructed by His Grace to show the grounds and be in attendance for the day. He conducted the party to the most interesting and beautiful portions of the park, thus saving a deal of labour and valuable time. The public being excluded from those portions of the estate which the party was allowed to visit, and none of them having been there before, gave the locality a peculiar interest.

The views are truly beautiful, varied, and extensive, and a richer field (photographically speaking) it would be difficult to imagine. An energetic worker, even with the most favourable weather daily, could not exhaust the field in a month. About fifty dry plates were exposed. The light, excepting for a short time in the forenoon, was everything that could be desired, and the hope was reasonably entertained that some very beautiful pictures had been secured.

The party left the grounds about four o'clock, and adjourned to the "Cross Keys," where a comfortable dinner awaited its arrival. Ample justice having been done to this, and after proposing the success of the Edinburgh Photographic Society and its out-door meetings, the party returned to town delighted with the day's excursion.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY.

At the meeting of the Association held on the 21st March, Professor VOGEL in the chair, the principal subject of discussion was a communication from Herr OBERNETTER on the gelatine emulsion process.

As regards sensitiveness, Herr Obernetter observed that it may be attained to any required degree by mixing isinglass and albumen with the gelatine, but the more sensitive the plates, the greater is the difficulty of preparing them, of guessing the right length of exposure, of developing, &c.: all the work must be carried on, it may be said at once, in complete darkness, and that is no easy matter. At the present time the author of the communication is in the habit of working with an emulsion requiring an exposure about one-fifth of that of ordinary wet plates, and for all purposes such a degree of sensitiveness is amply sufficient. For working with emulsion plates of this kind any dark room in which work is commonly carried on, and which is not too much lighted, can be used. The following are the formula:—

Ammonium bromide	28
Silver	44
Isinglass	25
Water	250

This is allowed to ripen for twenty-four hours, and another day is used for washing; then is added—

Gelatine (German)	25
Albumen	20
Water	750

The whole gives 1,000 emulsions.

The preparation is simple, but requires great care. The emulsion sets completely in about five minutes, and the plates can then be placed upright to dry in any place where the light is kept out. With the aid of calcium chloride or sulphuric acid the drying will take two hours.

The transport of dry plates in a state ready to be used Herr Obernetter was opposed to, because it is too troublesome for the sender, and too expensive for the consumer. He considered the preparation of the plates by his method, particularly when they have received a good cleaning in soluble glass, to be as simple and certain as that of ordinary collodion plates. In using the emulsion, however, the utmost care must be taken to prevent any access of light; all the slides, cameras, and dark room,

must be therefore perfectly light-proof. People imagine that all is right when they have dark yellow window panes or lampshades, and forget the think by the side of the door or window, which may cause any amount of mischief. With Nelson's gelatine and a fourteen-day emulsification, the author had attained as high a degree of sensitiveness as in the English plates; but an emulsion of this kind only sets at a temperature of from 5° to 6°.

The great point, in his opinion, is the rapid setting. He had not observed any of his emulsion to decompose or putrify, though he had had it standing in a warm room since Christmas. He believed that silver bromide must be an antiseptic, but to be on the right side, in anticipation of the coming warm weather, he now added some salicylic acid, which does not affect the sensitiveness.

Accompanying this communication Herr Obernetter sent some bottles of his emulsion, which were distributed to the members present for trial.

Professor VOGEL has experimented with some of Obernetter's plates, but, in consequence of his ignorance of the latter's formula for developing, he had developed them as best he could. Notwithstanding this, he had found them to quite come up to his expectation, and he showed a perfectly exposed negative which he had taken in one-fifth of the time of that required for a wet plate. He also showed a plate which had been exposed by Herr Obernetter on the 12th January last, and had been sent to him (the speaker) to develop; the same had given a perfectly pure negative—a view of an interior.

As regards the use of alcohol with gelatine emulsion, as recommended in the paper, Herr FAHLING remarked that he also had experimented in this direction. He had laid a freshly-coated gelatine emulsion plate in a pan of alcohol so soon as it had set, and found that the alcohol extracted all the water from the film, and occupied its place. The plate was quite dry in about two hours after its removal from the pan.

Dr. Vogel, however, remarked that Obernetter's emulsion treated in this way would dry in half an hour.

Herr SELIGMANN expressed surprise that Herr Obernetter should recommend the addition to the emulsion of albumen, which would certainly act as a restrainer. On one occasion, when, for the sake of experiment, he had himself prepared an emulsion of albumen, and had allowed the plate coated with it partly to dry spontaneously, partly to coagulate by immersion in a not too weak silver bath, he had found it to become so insensitive as to be useless.

The PRESIDENT pointed out that already in 1846, before the discovery of collodion, attempts had been made to obtain a negative on glass by means of an iodized film of albumen, when the same great want of sensitiveness of this substance was observed. Herr Obernetter, however, must have had a different experience, for it will be remembered that in the paper just read he laid great stress on the presence of albumen in the development; he had given particular instructions not to lay the plate in water before developing, with the object of preventing the albumen in the film from being dissolved out.

Herr HARTMANN read a very interesting and complete paper on the anatomy of the human head, with particular reference to everything that had an influence on its external appearance, and therefore of importance for the portrait photographer. For illustrating his paper, he exhibited a natural skull and a model of the muscles of the head, with a drawing on an enlarged scale of the same. He thought, however, that the veins and arteries of his model were made too prominent.

Dr. FRITSCHÉ explained that in the preparation of which the model was a reproduction, the blood vessels would be disproportionately distended in consequence of the injection to which they had been subjected.

At the next meeting of the Association, on the 4th April, Herr PRUMM, in a speech of great feeling, proposed that the honorary membership of the Society should be granted to the President, Dr. VOGEL. According to the statutes, the Committee of Management were empowered to confer this honour on men distinguished in science and art, and on those who had rendered special services to photography in general or to the Association in particular; to make this distinction still greater, it has been but sparingly bestowed. The completion of the tenth year of the existence of the Berlin Association for the Promotion of Photography seemed to the speaker to be a most favourable opportunity for the members to show the respect and

admiration they entertained for their president, to whom the flourishing condition of the Society was in great part due; and the most adequate way of doing so seemed to be to take advantage of the statute above alluded to. The Committee at their last meeting had come to the determination of electing their President, Dr. Vogel, an honorary member of the Society, and has begged the general body of the members to confirm their decision. The proposition was received with general acclamation, and three rounds of cheers for Dr. Vogel. In returning thanks, the latter explained that at first he had some hesitation in accepting this great distinction, the climax to all the proofs of devotion and love he had experienced from the members of the Association, because perhaps outside the Society it might be misinterpreted; but on consideration he felt that his conduct in following the example of Dr. Hornig could not be open to exception; the latter had also been nominated to the honorary membership of the Photographic Society of Vienna, whose president he is; he (Dr. Vogel) would therefore gladly accept the honour now proposed to him.

A letter was read from Mr. Muybridge, of San Francisco, whose instantaneous photographs of the trotting and galloping action of the horse had been shown at a previous meeting of the Association. He described in this letter the manner in which these photographs were taken—that is to say, by means of six cameras placed close to each other, and so arranged that the shutters were electrically opened at intervals of $\frac{1}{25}$ th of a second. The writer intends to submit other animals and also human beings to similar experiments, and hopes to attain results of great interest and importance to the student of animal mechanics.

Herr SELIGMANN reported on the results of his latest experiments with dry plates. He had exposed some of Wratten and Wainwright's plates in the studios of Herren Prumm and Schaarwachter, using the iron oxalate developer, and found the requisite time of exposure to be about one-tenth of that of a wet plate. The plates which were developed in the first named studio exhibited very nearly the same brilliancy and general characteristics as wet plates; those in the studio of Herr Schaarwachter were somewhat greyer in tone. This difference, in the opinion of the speaker, was due to the iron oxalate developer used at Herr Prumm's being freshly made, while that of the other studio was some days old—another proof that this developing solution, to be effective, must be recently prepared for use. He had likewise tried plates by Messrs. Wegner and Motter, and was able to speak in their favour. Herr Schaarwachter also exhibited some negatives on gelatine pellicles that he had received from Herr Wilde; they are prepared as follows:—A glass plate is first coated with raw collodion, then with gelatine, and next, after being dried, with emulsion. It is then exposed, developed, varnished, and the pellicle finally drawn off the glass.

Herr KUNTZE submitted some plates in which he had found a number of peculiar small black spots. This imperfection he believed to be due to too great acidity of the silver bath, for when the latter was neutralised with bicarbonate of soda the defect disappeared.

Herr REICHARD doubted whether the acid was the cause of the spots, for silver baths had been often for some reason or other acidulated to an excessive degree without producing a similar appearance.

Herr SCHAARWACHTER'S experiences agreed with those of Herr Kuntze. An acid silver bath with a neutral collodion produced the spots, but when the collodion was also made acid, then the evil was cured.

Herr PRUMM took occasion to impress on the members present the importance of bringing up for discussion at the meetings of the Association the numerous defects that were observed in the collodion process, as affording the best opportunity for learning how to get rid of them. At the present time, photographers in Berlin had to complain of two causes of the bad or inferior results of their work: one of these was the town water, which, since it had been derived from a new source, was everywhere disapproved of; the other was the collodion, which seemed lately to be subject to loss of colour. To obtain good photographs with such a collodion, it must necessarily be acidulated, and that to a degree never previously attempted; also the acid must be kept continually renewed. As regards the spots to which Herr Kuntze had drawn attention, the speaker would have been inclined to seek for the cause in the albumen substratum, were it not that they had been found also on plates in which a substratum had not been

used. Dust particles, especially those in which lime occurred, were very likely to produce spots on albumen, as he had himself often had occasion to observe. Generally the alkaline action of lime must be prejudicial, and the presence of lime in cotton wool, which had been spectroscopically demonstrated by the President at one of the meetings of the Association in the summer of last year, might be the origin of many an imperfection.

Herr QUIDDE complained that in winter, particularly when it was a cold one, he had to contend with many causes of failure which disappeared with the coming of a warmer season; this was especially the case with defects in the collodion, which also were now more common than formerly.

Herr JOOP related the case of a laboratory where the work had always been satisfactorily executed, until one day suddenly all the plates showed signs of fogging. This was found to be due to the fuel used for heating the room; formerly this consisted of coal exclusively, but was changed to brown coal and anthracite, and from the date of the change the fog made its appearance, but vanished again when wood was burned in the stove.

Herr BOLL believed that in this case defective heating appliances must have been at fault. He had himself always used anthracite as fuel without observing his plates to fog.

Herr VON ROUZELÉN pointed out a circumstance which rendered the discovery of the cause of defects extremely difficult. The photographer never knew what occurred to his chemicals when his back was turned. It often might happen that a half-educated assistant, partly out of ignorance, and partly out of inquisitiveness, would tamper with the reagents, and thus become the author of inexplicable failures.

Herr SELIGMANN exhibited a travelling camera constructed by Rouch, in England, for plates ten inches square. The same he showed to be exceedingly convenient and compendious, and to pack into a space of 12 inches square by 3 inches high. It could be bought, he said, for 120 marks (£6), but he had found it necessary to introduce many improvements, which increased the price by 80 marks (£4). Some of the parts, he thought, were decidedly too weak, and he had replaced them by others of stronger construction; he had also made some additions to improve the stability.

The meeting closed with the reading of the annual report of the committee of management; the financial statement was read by Herr BERGMANN, the report on the library by Herr HARTMANN, and an account of the condition of the portfolio by Herr SELIGMANN.

Talk in the Studio.

"BRINGING HOME THE MAY."—One of our comic correspondents pays Mr. H. P. Robinson the compliment of quoting the title of his famous picture "Bringing Home the May," as the side-heading to a comic sketch illustrating the chilly, unseasonable weather.

To Correspondents.

F. B. Y.—In your second batch of prints the toning bath is almost too new and active, and the negatives are not good. They are not quite brilliant enough to permit sufficiently deep printing to give a rich well-toned print. The bath will improve daily. We see no reason to condemn the paper.

H. W. H.—We should not think that metagelatin is the best substratum to collodionize plates, on account of its slow setting qualities. It may be made by long continued application of heat to the solution of gelatin, with or without the addition of a little acid. Diluted albumen forms the best substratum we know. 2. So far as our experience goes, the sulpho-cyanide of gold toning bath is quite safe. We have only used it for collodio-chloride prints, and have never known a case of fading. There is no such decomposition or liberation of sulphur as should cause apprehension.

CYMRIG.—A piece of wood with a strip of pure black india-rubber (not vulcanized) cemented on its surface is the proper thing for a water-tight top to a silver bath. This will not injure the solution; almost anything else will do so.

T. GRESHAM.—Thanks for your suggestion, which we will print in an early number. We do not know of any English translation of the French manual in question; any English bookseller will be able to order it through an agent. There are various foreign publishers in London who will undertake such agency, such as Trubner, Dulau, and others. The price we do not know. The duplication you point out is somewhat amusing. Probably some contributor to the *Times*, rather than the managers of the journal itself, neglected to make the necessary acknowledgment. A little more exposure, or a brighter light, is the chief want of your prints.

OPERATOR asks where directions for the preparation of rapid gelatin plates may be found. We are almost tempted to ask where, in the photographic literature of the last twelve months, such directions cannot be found, as this has been the staple subject to which discussions in societies and articles in journals have been devoted; and in our YEAR-BOOKS and in the NEWS for the last few years many articles have appeared. One of the most rapid of published processes is that of Mr. Bennett, described on p. 511 of our last volume. 2. Captain Abney's book will give you full information. 3. Both the emulsion, the sensitive pellicle, and the plates are procurable, as you will learn on examining our advertising pages. In our last YEAR-BOOK you will find the fullest collection of advertisements referring to the subject.

CHROMOTOPILOTS.—We cannot give you certain information as to where or how the paper is procurable, but will endeavour to ascertain. Our accounts of Boll's researches in relation to "visual purple" are derived from foreign scientific journals as they have appeared from time to time. Accounts of such matters relating to foreign science are contributed to our pages by members of our staff who read the various foreign journals for the express purpose of condensing anything of interest to our readers.

AMATEUR.—There is no work devoted to the subject of backgrounds or to special effects in backgrounds or modes of obtaining them.

J. C.—We have not any definite information as to the comparative excellence of French and German mounts. We think it is probable that there are good and bad produced in each country.

GLASS-HOUSE.—To secure a north side light it is of course necessary that the house should stand due east and west. The ends being east and west should be opaque, and south side may have glass to be excluded by blinds when the sun shines; but will be useful without blinds in dull weather.

J. B. D.—It appears to be generally conceded that more rapid results can be obtained with gelatin than collodion; but that collodion emulsions are more manageable. For details of a good collodion emulsion read Mr. Cooper's article in our YEAR-BOOK.

O. P.—Many thanks. We will give the suggestion in an early number.

ANXIOUS.—There is really no difficulty in producing collodion positives either on glass or on ferrotype plates; but you must get rid of some of the cardinal ideas in producing negatives. Your chief fault appears to be a tendency to over-develop. Positive development must be much more rapid than that necessary for negatives. Try again, bearing this in mind.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

WOLFRAM'S INVESTIGATIONS OF PYROXYLINE—THE CHALLENGER AND POLAR EXPEDITIONS DEPICTED BY PHOTOGRAPHY.

Wolfram's Investigations of Pyroxyline.—A paper upon pyroxyline that appears in *Dingler's Journal* can hardly be passed over without remark, albeit, in the face of other results by well-established authorities, these last researches must not be too readily received in all their integrity. The author of the paper, a German chemist, M. G. Wolfram, tells us, in effect, that there is only one description of pyroxyline or gun-cotton, whereas, as our readers know very well, we have hitherto distinguished two broad classes, that may be roughly termed soluble and insoluble. The former is photographer's gun-cotton, a lower compound (that is, less nitrated, or containing less nitrogen) hitherto known as di-nitro-cellulose; and the military gun-cotton, or tri-nitro-cellulose, that is more highly charged with nitrogen. It may happen that the military gun-cotton is, to a certain extent, soluble in ether and alcohol, just as photographer's cotton is found sometimes not to be wholly soluble; but, as a general rule, the two kinds may be described as soluble and insoluble, and are regarded as finished products in their way. According to M. Wolfram, however, there is only one real nitro-cellulose, and that should contain 41.89 per cent. of NO_2 , or nitric oxide. If a cotton, after treatment with the acids, is found to contain more NO_2 than this, then the surplus nitric acid is in the pores, and can no longer be regarded as a component part of the gun-cotton. Again, if the steeped cotton proves to contain less than 41.89 per cent. of NO_2 , then the conversion of the cotton is not complete, and there will be found mixed with the gun-cotton a certain proportion of non-nitrated cellulose. This is M. Wolfram's chief statement, and it differs, we need hardly say, from what has already been laid down by authorities on the subject. It is certainly a fact that samples of photographer's gun-cotton can be produced which are entirely soluble in alcohol and ether, and which are no other than di-nitro-cellulose, or, in other words, the lowest form of pyroxyline, and contain, therefore, according to M. Wolfram, non-nitrated cellulose, or unconverted cotton. If they contain non-nitrated cellulose, how is it, we ask, that the mass dissolves so readily and without residue? This is a point that we should like to have more fully explained, for if we can prepare a product from cotton which will entirely dissolve in ether-alcohol if it has not been acted upon too much or too little by certain agents, there is surely good ground for calling such product a definite and finished body. M. Wolfram says no, it is imperfect; and, to render it perfect, it must contain more than double as much nitrogen, and become what he calls pentanitro-cellulose. This, however, is insoluble; hence we are to conclude that what photographers call pyroxyline is not really so, but gun-cotton mixed with ordinary cotton. We do not think many chemists and photographers will be found eager to believe this, but we are bound to say that M. Wolfram's statements are not all of them so difficult of credence. In fact, in one portion of his paper he seems to bear out a statement that is made by Dr. Van Monckhoven in our last YEAR-BOOK. Dr. Monckhoven therein shows how that one and the same pyroxyline may be employed both for dry and wet plates. For dry work a more pulverulent film, and one easily permeable by reagents, is desired, than is necessary for wet plates. To prepare a pyroxyline proper to dry plates, the acids are dilute and the temperature very high, when the result is a gun-cotton of a pulverulent character and in short fibres, yielding a film that is no longer transparent, but semi-opaque and

porous. Strong acids and a low temperature, on the other hand, give a pyroxyline that yields a colourless and resistant film. But either a semi-opaque and pulverulent film on the one hand, or a transparent and resistant one on the other, may be secured from the same gun-cotton, Dr. Monckhoven tells us in his paper, if care is only taken to modify the nature of the solvents employed. M. Wolfram confirms this statement of Dr. Monckhoven, and says distinctly that the film formed by evaporating a solution of pyroxyline is not merely dependent in its character upon the pyroxyline itself, but upon the solvents employed. M. Wolfram further says that the solubility of a gun-cotton is considerably influenced by the attack of sulphuric acid employed. The sulphuric acid has the effect of toughening the fibre, and the more easily a cotton fibre is toughened, the more difficult is it to turn the fibre into gun-cotton. One other point deserves attention in M. Wolfram's paper, especially by photographers. A little while ago, as we know, there was a good deal said in the photographic world about the addition of gelatine to cotton in the preparation of dry-plate gun-cotton, Colonel Stuart Wortley being one of the advocates of such a measure. The collodion film was thereby improved and rendered more sensitive, it was averred, although it was evident to all that the gelatine must have been dissolved on the addition of the acids. M. Wolfram, however, in his paper, tells us that a pulverulent pyroxyline will be secured by this means, and a pulverulent pyroxyline is, as we know, of all things the best suited for dry-plate work. By impregnating cotton with gelatine, he says, or by adding gelatine to the acid mixture previous to nitration, this modification of the pyroxyline is brought about. It will be interesting to see how far M. Wolfram's published investigations will be challenged in this country and abroad.

The Challenger and Polar Expeditions Depicted by Photography.—People are beginning to call out about the photographs of the Challenger expedition. It is now a long time since Sir Wyville Thompson returned from the cruise, and brought with him a valuable collection of negatives, made in every habitable and inhabitable corner of the globe. A large sum of money has been granted by Government for the printing of these negatives, but so far, it seems, no distribution of the pictures has taken place. We trust that, unlike the pictures of the Polar Expedition, they will not be printed in silver, but something less perishable. As their value lies more in the fact that they are records than anything else, permanence is an element that should not be forgotten, and seeing that there are several methods of permanent printing at our disposal, it is foolish in the extreme not to avail oneself of them. In the case of the Polar photographs, the pictures, although taken by public money, were kept out of the hands of the public in a most jealous manner. The few sets printed in silver were handed over to certain societies and institutions, in ill-contrived boxes, that hindered their inspection, and those who obtained the privilege of purchasing were asked to pay very much more than their cost. As to permitting the general public to purchase what was their own at cost price, such a thing seems never to have entered the heads of the Secretary of the Admiralty, or whoever else had the direction of affairs; and although the Polar negatives might have been duplicated a dozen times over if need be to supply impressions, the pictures are still rarities in their way. Whether the same narrow and parsimonious policy will be adopted in respect to the pictures of the Challenger Expedition remains to be seen; but as many of them possess distinct scientific interest, we shall probably have the scientific societies calling out unless the prints are properly distributed. Again, we hope that silver printing has been discarded, for unless the albumenized paper now manufactured is properly selected, no dependence can be placed upon the results. A series of prints upon cheap foreign paper would be of little value in the archives of a museum.

FRENCH CORRESPONDENCE.

REPRODUCTION OF COLOUR BY PHOTOGRAPHY—PROCESS OF M. CH. CROS—PROCESS OF M. DUCOS DU HAURON—THEORY AND PRACTICE OF THE TWO PROCESSES.

Reproduction of Colour by Photography.—There can be no doubt, I think, that the attention of a large number of experts is at present occupied with the problem of reproducing the natural colours by means of photography. The late Duke de Luynes, who had a steadfast faith in the ultimate solution of this problem, left by will a bequest of a considerable sum of money to be given as a prize to the discoverer of a means of fixing in the camera the colours as they are seen on its ground glass plate. It was argued by this noble patron of our art that as the human intellect had been able to obtain from light a spectrum with all the lines and colours completely rendered, so it must arrive at the point of compelling nature to surrender the other half of her secret. Since his death no one has ventured to claim the promised reward; it is still waiting like a rich heiress on whom a number of suitors are in attendance. The family of the testator, however, are so anxious to carry out his wishes that they wanted to give a portion of the accumulated interest of the legacy to M. Ducos du Hauron, who has achieved an approximation to the solution of the interesting question. It may be accepted as a true approximation, since the process of M. Ducos du Hauron is in perfect harmony with scientific principles; it is founded absolutely on the complex nature of the natural colours. M. Ducos du Hauron works on precisely the same lines as M. Ch. Cros, who so far back as the 23rd November, 1868, took out a patent for what he called "Colours in Photography—solution of the problem." The latter part of this assertion was perhaps slightly strained, but it remains a fact that M. Ch. Cros was the first to announce the ingenious process the discovery of which was effected simultaneously in two quarters. In the PHOTOGRAPHIC NEWS of the 16th May last, at page 229, the manner of working the application of the principle (for the processes both of M. Cros and of M. Ducos depend on the same) is explained—the building up of the natural tints by the superposition of three mono-chromatic prints. First a red, next a yellow, and then a blue print is taken, for by the use of these three colours the painter obtains all the tints that he requires, and it is by the decomposition of light into the same colours that we get the phenomenon of the spectrum. M. Ducos du Hauron, precisely the same as M. Ch. Cros, has taken advantage of a well-known law of physics in order to obtain the infinite variety of the tints of nature by combining in different proportions these three primary colours as they are called. As will be seen, the process is based on natural principles, and on that account it deserves serious consideration; but the question will be asked, will nature allow herself to be thus overcome, and will she in the end yield to these irrefutable arguments? It may be hoped so: she is an indulgent goddess, and when a part of her wealth has been taken by force, she often generously gives the rest of her own accord. In my last letter I alluded to the circumstance that very often the same discovery had been made in different quarters simultaneously, because it meets a want of the time. This is again the case with the invention of M. Ch. Cros and M. Ducos du Hauron, two investigators who were previously quite unknown to each other. Always true to the principles of justice, and without personal considerations of any kind, I shall endeavour impartially to place to the credit of each of these the share that is his due. I would not allow Daguerre and Niepce to be separated, because the facts of history can never be permitted to give way to considerations prompted by the spirit of provincialism; in the same way I cannot separate the two men who have opened up the road to the discovery of "Natural Colours in Photography." It becomes,

therefore, a peremptory duty to make known separately the considerations which M. Cros and M. Ducos adduce in support of the discovery. They may serve as a guide to those who are taking up the question, and may shed some new light on the facts which are already known.

Process of M. Ch. Cros.—To give his own words:—"In attacking the problem, I start from the following proposition, of which I shall give a proof: colours are principles which, like solid bodies, have three dimensions, and which, consequently, require three independent variables in all formulæ by which they are represented. It follows from this that if we had an instrument for measuring colour the same as the thermometer measures degrees of heat, it would require for each of the tints three distinct numbers to express their relations with one another. Hence, a figured analysis of any given subject or painting might be possible on such plan as this:—The surface could be divided into a number of contiguous squares, sufficiently small for the degree of detail required, and each of these could have their correct tint indicated by means of three figures. Thus each point of the picture could be measured by means of three magnitudes which could not be confused into one number. It may, therefore, be said that a painted picture has five dimensions, two for fixing the elemental points of the drawing, and three for giving the value of the tints. What, then, is registered by the photographic instrument? Nothing but the actinic intensity of light, which is translated into black and white and the intermediate greys. A single linear scale would be sufficient to determine each of the terms of this series from black to white; an ordinary photograph gives no indication of colour. The three kinds of primitive colour are the red, the yellow, and the blue. It becomes, therefore, necessary to take three different prints, one of all the points more or less red, a second of all the yellow points or those containing a proportion of yellow, a third of all the points containing blue. When we have obtained these three photographs they will be one of uniform tint, like ordinary photographs, but in the different shades of black and of grey; more or less dark they will respectively express the different qualities of all the red, all the yellow, and all the blue, that there is in the picture. Thus, then, we shall have obtained, as a whole, all the information that the given picture is able to afford, but not its reproduction at one direct glance. In other words, we have the analysis of the colour of the picture, but not the synthesis." To obtain this kind of analysis of the different coloured rays proceeding from the same picture, M. Cros makes them pass through stained glass. The synthesis consists in superposing the three positive prints one over the other on a white or transparent surface, so as to produce a constant result visible without the interposition of any optical instrument. For this purpose he has recourse to three heliographic plates on stone or steel taken from the three negatives, and from these he obtains positive prints. The dark parts of the red print, for example, represent the parts of the picture where the red has least acted, the light parts of the print those where it is most pronounced. This print, which is called the red print, is pulled in the complementary colour of red—that is, in green; similarly the yellow print is taken in violet, and the blue in orange. The second and third of these prints are taken on transparent plates, so as to allow the tints below them to be seen. "In practice," further writes M. Cros, "it will be probably better to take the negatives by means of the green, violet, and orange rays, and to pull the prints with red, yellow, and blue colours. It will also be well to begin with the print in blue, for transparent blue lakes are rare, but the yellow and red pigments can be more easily diluted. The final complete print, taken in this way, by a method resembling that of chromo lithography, preserves in its combined tints the same relations as those of the original picture, except that each of the colours will be, to a slight extent, lowered by a tinge of its respective com-

plementary, and this will produce a general effect, as if a bistre ground had been used. In those spaces where none of the colours have acted, the three prints will show the maxima of colourization, and superposed they will produce black; where the three colours have manifested the most intense action the three prints will allow the white of the paper to show through. Pursuing the analysis, it is easy to see how the secondary and tertiary tints will be produced."

Process of M. Ducos du Hauron.—The above is a summary account of M. Cros' method; let us now note that that of M. Ducos du Hauron rests on exactly the same chain of reasoning. Granted the principle that simple colours can be reduced to three, M. Ducos argues thus:—If I can decompose into three distinct pictures—a red one, a yellow one, and a blue one—the single picture which I am going to copy, but which is in reality a triple picture as far as regards the colour rendered by nature, and if of each of these three pictures I can obtain a photographic copy which reproduces its special colour, it will be enough for me to combine these three coloured images into one image to obtain an exact and faithful reproduction of the original as regards both colour, modelling, and general effect. Starting from this hypothesis, M. Ducos du Hauron, after many experiments, has succeeded in obtaining separately with the camera three negatives of the same subject, each taken by a differently coloured light—a green light, a violet light, and an orange light. These negatives he calls his monochromes; the green light gives the red monochrome, the violet light the yellow monochrome, and the orange light the blue monochrome. These are the complementary colours. "Let us take, for instance," says M. Ducos du Hauron, "the red monochrome produced by the negative taken with the green light. Since the cell filled with a green liquid acts a filter for light of that colour—that is, allows the green rays almost exclusively to pass, and intercepts the greater part of the other rays in proportion as their tone approaches more nearly that of the true red, and since, on the other hand, these natural objects, which emit abundantly the green rays, are coloured yellow, green, and blue, it follows that the negative in question will translate into black all yellow, green, and blue surfaces: also that the red pigment of the monochrome taken from this negative will translate into red the reds of the model, and that a red the more intense in proportion as the red of the model is more decided; lastly, that this red pigment will be eliminated beneath the black parts of the negative—that is to say, in the parts of the monochrome corresponding to yellow, green, and blue surfaces—and that this elimination will be the more complete in proportion as the yellow, the green, and the blue are more decided. Analogous reasoning applies to the other monochromes: each will contain its proper proportion of the special colour it is intended to represent, either in a simple or combined form." By superposing these three monochromes—the red, the yellow, and the blue, we obtain the synthesis—that is, the polychromatic image. Everywhere there will be formed a combination of red, and yellow, and blue in unequal proportions. The red, yellow, and blue rays transmitted or reflected by natural objects are all compound, although they produce a simple effect on the retina of the eye. There is always some other colour in our reds, our yellows, and our blues, and for this reason the mixture of our colouring substances are able to render the orange, the violet, and the green. In order to obtain as accurate a reproduction as possible of the natural colours, the three monochromes, or positive images to be transferred to a white ground, must be worked up with the purest pigments; the red should be the result of the entire absence of all green rays, the yellow that of all the violet rays, and the blue that of all the orange rays. For working, the processes employed are those of photographic printing in colours, with coloured gelatino-bichromate and other similar methods; prints may also be got by using

perchloride of iron instead of bichromate. We may also produce the three monochromes chemically by separately focussing on three plates with different salts of silver Chromo-photography depends, therefore, really on the decomposition of light in the way indicated above, a way which is certainly complicated, and appears to admit of very little simplification. "This decomposition or filtering of the light may be either physical or chemical—physical when it is effected by the use of coloured media (coloured glasses, prisms &c.); chemically when we can produce it by means of photographic compounds which are sensitive only to the colours of certain parts of the spectrum to the exclusion of all others."

Theory and Practice of the Two Processes.—I have now explained the principles on which the two inventors have worked—principles which seem to me to be fully established, and to admit of no contradiction. As regards practice, there is room for infinite variety, and it is for the practitioners and specialists to look for the methods of obtaining the best results. M. Ducos du Hauron has on many occasions shown the results of his patient research and indefatigable study. M. Ch. Cros has not gone beyond publishing his theoretical notions; he wishes those who have a liking for the subject, and who possess the means, to enter on the field of practical experiment, of which he does not endeavour to conceal, but rather avows, the great and manifold difficulties. He recognizes, moreover, that it is not enough to merely superpose the three prints on which his system is based; this would be merely eluding the correct solution of the problem. Now to M. Ducos du Hauron belongs the indisputable merit of having carried the entire arrangement out of the region of theory into that of practice. So soon as the processes of photography are so far simplified that every one, without necessarily being a technical photographer, can work them, it is to be hoped that other savants will turn the discoveries of M. Ch. Cros and Ducos du Hauron to account. Gradually the photographic camera finds a place in the laboratories of our most celebrated scientific men, and it does not appear too much to expect that one fine day, and that very soon, the world would be startled by the news that the great secret of all has at last been discovered. Then photography will have found the link still wanting to render it a complete art, and some lucky experimenter will claim the prize left by the Duke de Luynes, as well as receive the meed of public acknowledgment.

K. VERSNAEYEN.

REPLY TO THE PAPERS READ AT LAST MEETING OF THE SOCIETY AT THE "DISCUSSION ON GELATINE EMULSIONS."

BY C. BENNETT.*

In the first paper read at the last meeting of this Society, the theory which was started, that the action of long emulsification was to reduce fog, appears quite feasible, provided the salts are so proportioned as to induce fog. This, however, I have never proposed; my aim has been in the opposite direction, and I am fully convinced that from the first hour of emulsification fog should not and cannot exist in a properly proportioned emulsion. The theory of the particles of silver bromide becoming finer by emulsification, and in consequence of the greater surface presented to the action of light more sensitive, is one that I would willingly grasp were it possible, but under no power of my own microscope have I been able to detect any difference in an emulsion during the earlier or later stages of emulsification. When an emulsion is lightly salted, I observe that the particles are infinitesimally fine, and remain so, however long the emulsification may be. When heavily salted, they are coarse and remain so—at least, such is my experience. We must all hope Captain Abney's continuous experiments may throw more light on these particulars, because these experiments

enable practical workers to arrive at their conclusions with greater ease; and although I cannot say my own experience exactly tallies, I feel sure these and similar experiments must ultimately end in the solution of the problem of long emulsification and increase of sensitiveness: points which, in connection both with gelatine and collodion, are of the highest importance. I cannot exactly comprehend that where the particles are in contact, as Captain Abney states, the reduction of the adjacent unexposed particles can possibly follow so rapidly upon the reduction of the exposed particles as this portion of the theory would seem to require. In reality, when the film is flooded with pyro, the fog is produced evenly and simultaneously over the whole surface, and does not, as might be supposed from Captain Abney's theory, spread from a high light on to a shadow. I speak of fog under the condition laid down by Captain Abney, namely, when the particles are coarse and in contact. I hope Captain Abney will soon be in a position to bring forward as a fact that which at present he treats as a theory.

With regard to Messrs. Bedford and Fry's remarks respecting the coloured light to be employed with gelatine plates, I believe both gentlemen alluded to development only, and not to the making of the plates. I can only say that with less than two thicknesses of ruby glass (except with artificial light) I should fail entirely to make the films; and respecting orange glass, I may certainly not have procured the right description, but I have never met with a sample which, even when three or four thicknesses were used, would enable me to coat or develop with safety. I do not, however, stint the light, provided it be of the right colour; the only colour I find in practice to be efficient is deep ruby, and of this I find I can use any quantity without fear, but prefer four square feet of four thickness, to one square foot of one thickness. I speak as a practical worker, and repeat that I presume Messrs. Bedford and Fry allude only to development when they recommend orange light. For that purpose it is quite possible, by adopting suitable means, to cut off the direct rays from falling upon the plates to utilize Mr. Fry's plan, but where extra rapid results, necessitating a powerful developer, are sought for, the orange paper or glass would assume a decidedly dangerous phase. I find that Captain Abney, in a letter to the *Journal*, states that orange glass, no matter of what density, must eventually produce fog, and gives his reason why this is so. I am glad to say that in practice I find my own results entirely corroborate this statement. Each operator must then decide what amount of actinic light he can afford to admit into his dark room, and place in the imaginary scales on the one hand "convenience of working," and on the other, "quality of result," and strike a balance, and as there will no doubt be many opinions as to what constitutes perfection of results, so we may expect to find many different views as to the description of light to be used with gelatine films. I have not yet had time to test Colonel Wortley's addition of nitrate of uranium to the emulsion, so will leave that portion of the question. Colonel Wortley has stated that he found his plates as rapid as mine, though they had not been emulsified for so long a period, and attributed that to the manner of washing. Colonel Wortley will remember that the plates I exposed against his were described at the time as having been prepared from an emulsion which had been rinsed out in only three changes of water, as my inlet and outlet pipes had been frozen a couple of months; the plates, therefore, can scarcely be taken as a fair test of long emulsification, and the action of Colonel Wortley in bringing them forward as examples is calculated to mislead.

Mr. H. B. Berkeley's paper "On Gelatine Emulsion, with Excess of Silver," confirms all I have previously said with regard to the cause of red fog, which, wherever it exists, destroys all sensitiveness. It has been shown, over and over again, that free silver is not necessary to the highest degree of sensitiveness; why, therefore, continue to use it in the face of such a long train of evils?

I entirely agree with Mr. Fry's remarks, that the effects

obtained upon properly prepared gelatine films are more uniform, and require less local treatment than is the case when collodion is employed; this, I think, corroborates my argument to Captain Abney, that local development, as in collodion and bath plates, is not necessary; and, as Mr. Fry states further on, "they do not require that separate parts shall be reinforced, the correct gradations being a striking characteristic of the system." I feel sure, at the time these words were spoken, Mr. Fry had no idea of ever supplying them commercially, and so only spoke as one who had used gelatine films in the studio; but it is a point I have always contended, that the more sensitive the film, the more equable is the action of light, and the more correct are the gradations. The negatives shown by Mr. Wainwright also were a telling proof that want of latitude in exposure is not one of the characteristics of the gelatine process.

I am sorry this subject has been so prolonged in its discussion, but cannot fail to notice that at the last meeting, although a second was evening devoted to the same subject, the interest appeared as keen at the last minute of the hour as at the first, which can only be attributed to the fact that the interest was on a vital point, namely, dry-plate or silver bath, not only for the field, but the studio.

COLLODION TRANSFERS.

BY W. T. MORGAN.*

At a recent meeting of this Society, as most of you are aware, a very interesting paper was read by Mr. Foxlee on the subject of enlargements. During the discussion that ensued, the question arose as to which is the best mode of making large pictures. I remarked that for all moderate sized enlargements (say 20 by 16) I preferred the collodion transfer as possessing many advantages over all other known methods of enlarging. Mr. Simpson then suggested that I should prepare a paper on the subject for this meeting; but, as I have nothing new to bring forth, but what every photographer knew, I could not see how I would profitably occupy the meeting. It was then proposed that I should explain my method of working. This I will do with much pleasure.

I maintain that collodion transfers possess many advantages over all other known methods of enlarging, not even excepting the secret five pound, ten, or fifteen pounders. In the first place, there is the facility by which they can be produced; secondly, great variety in the choice of material to which they can be transferred; and, thirdly, superiority of the finished picture. I will give an instance of the first-named. An officer in the army came to my place one morning, and asked me whether I could make him a large picture to match one he had of his wife, size 14 by 12. He was proceeding to India by the evening mail, and wished to make it a present before he left. It was to be painted, framed, &c., at latest by 7 p.m. the same day. This, of course, I told him was out of the question; the light was then too poor even to make a large negative, without the *et ceteras* attached, and the most I could attempt was to make him a few *cartes* by the time named. He sat for the *cartes*, and I got a tolerable negative. In the course of conversation, he mentioned that he would not care what he paid if he could get what he required. Now, as necessity is universally acknowledged to be the mother of invention, so in my case I began to lament that I could not transfer a little of the useful that appeared to be so plentiful with him and so scarce with me. It then occurred to me that it might be done by collodion transfer, so I set to work with a will. In half-an-hour the transfer was made, in less than half-an-hour more the artist was at work at it, and before 6 p.m. it was fairly painted in oils, framed, &c., and eight guineas paid for it, to our mutual satisfaction. I think this is a fair sample of the facility by which they can be produced.

* This paper was originally read before the South London Photographic Society, and we reproduce it here as the clear statement of a practical man, for the benefit of many who have asked us to reprint instructions for this method.

Then, on the score of variety, they can be used as transparencies, or, if for working in crayons, they can be placed on coarse drawing papers of any tint; if for water colours, on smooth papers. This can be transferred to ivory for miniatures, or to canvas for oils; but if for plain pictures, I think there is nothing more beautiful than transfers upon the eburneum, as practised by the late Mr. Burgess, of Norwich. In the next place, there is more rotundity, better texture, and more detail in the finished picture, and without that very objectionable thickening of the hair, spreading of the high lights, and general flatness, that always prevail in the enlarged negative by the ordinary process.

This is my system of working; but, as I before mentioned, there is nothing either new or novel, but simply plain, practical experience. Coat a plate with either Huggon's, Mawson's or any good collodion—if great softness is desired, newly iodized; if for vigour, a month or two old will be the best. Expose three or four times longer than would be required for iron development. Develop with the following:—

Pyrogallic...	100 grains
Citric acid	60 "
Glacial acid	2 ounces
Water	20 "

The development must be stopped immediately all the detail is well out, without there being too much vigour on looking through the picture as a transparency. Wash well, and fix with cyanide as for negatives; wash well again, and then pour over the surface the toning solution. Sometimes, when the negative is every way suitable, the light good, and all things favourable, the picture will develop with an agreeable tone, and will not, in that case, require further toning; but this is not always to be relied upon. One of the principal drawbacks to the more general adoption of collodion transfers is the very objectionable cold blue-black tone that usually pervades them. I have tried all kinds of toning—bichloride of mercury, uranium, sulphocyanide, and almost everything else that has ever been suggested—but for all practical purposes I have found this to be the most simple and effective:—

Neutral chloride of gold...	...	1 grain
Water	...	1 drachm

This will tone the picture almost immediately, and give a rich tone if the picture was well exposed and thin; but if the development was slow from the exposure being short, then the picture will gain in density, and will generally be of an unpleasant blue-black tone.

After toning, pour off the solution into a measure, and flush the plate with a little water to save all the gold possible, as it takes very little to tone the picture. Wash the plate thoroughly well, and proceed to transfer, or lay the plate in a dish of clean water till a more convenient time; it will take no harm for a few days if kept immersed. To prepare the paper, take toned drawing-paper, or any other kind you may fancy, and float for about one minute on the following whilst warm:—

Gelatine	2 ounces
Water	2 pints
Chrome alum	60 grains

Then hang up to dry in a warm place. When the paper is once dry the film of gelatine will not again dissolve off, owing to the chrome alum making it insoluble; it will, however, after soaking a few minutes in tepid water, until it becomes slightly tacky.

To transfer the delicate collodion film from a large plate to rough paper must appear to the uninitiated a most formidable and delicate manipulation; but it appears much more difficult on paper than it really is in practice. The following will be found a very simple plan:—Soak a suitable piece of the above-mentioned paper in tepid water for a few minutes. Whilst this is soaking pour over the plate a solution of ten drops of nitric acid to one ounce of water, and flow backwards and forwards for a few seconds; this ensures the film leaving the plate more readily. Then apply your transfer paper, carefully avoiding air-bubbles, &c.; rub

it down into perfect contact with a squeegee. Care must be taken that the paper does not move after being once in contact with the film, as this would entirely spoil the picture. I always turn the paper over the edge towards the left, and holding with thumb and finger draw the squeegee across from left to right, then lay aside in a warm place until the paper is surface dry (that is, dry to the touch); lift one corner, and, if sufficiently dry, the film and paper will leave the glass and peel off quite easily. This will produce a matt surface, but when a highly-polished surface is desired the plate should be rubbed (before coating) with a little wax dissolved in ether, and the paper and film allowed to dry thoroughly; then pass a penknife round the picture, and it will immediately leave the plate with a very bright surface. Mount them as soon after leaving the glass as possible, as they soon curl up and become as tenacious as a watch-spring, and very difficult to mount at all, owing to the collodion surface not expanding after being once dry. With a slight wash over of a weak solution of gelatine they take water or any other colours quite easily, and, if desired, they can be "Vander-Weyded." There appears to be a great difficulty in obtaining enlargements on canvas. I have found the collodion transfers answer the purpose most admirably by preparing the canvas with the gelatine and chrome alum as before mentioned.

Now, I have another way of making transfers, and this, undoubtedly, is the best; but, like most other good things, it is rather difficult to get at. Coat the plate with Thomas's or Mawson's collodion. I prefer it after being six months iodized, and rather thick. I prefer the silver bath fifty grains to the ounce, but any good working bath will do. Let the plate remain rather longer in the bath than usual; remove the plate, and wash off all free nitrate under an ordinary tap; and, finally, wash with a little distilled water. Then, for the preservative, take—

Tannin	6 drachms
Honey	4 "
Water	20 ounces

Mix with hot water, and filter. Take a little of this in a clean measure or cup and flood the plate, pouring it off and on three or four times; then place the plate in a dark, warm place to dry, and store away for use. I have found these plates keep well for a month, and I dare say others will keep longer. When you require the plates for use proceed in the same way as for wet plates, but giving about six times the exposure; or, perhaps, the best way is to try a small plate first, and see as to exposure; or, better still, as a guide, is when a slight trace of damage is just visible on the plate before developing. Moisten the plate well with distilled water, and develop with the following:—

Pyrogallic acid	40 grains
Citric acid	20 "
Tartaric acid	20 "
Water	20 "

Flood the plate with this, and pour back into the measure, then add one or two drops of a thirty-grain solution of silver. If the picture comes up without density and full of detail, add a little more silver; if strong and without detail, add more developer. Develop rather deep, as the toning reduces the picture a little; then tone and fix with the following:—

Sulphocyanide of ammonia	5 ounces
Chloride of gold	5 grains
Water	20 ounces

Flood the plate with this, and pour on and off until all yellowness disappears, then thoroughly wash, and transfer in the usual manner.

The small crystals before you were done in this manner. I have made many better as regards tone, &c. I much regret I have not been able to make an enlargement by this method in time to show you this evening, but I can safely say that when it is carefully worked with tact and judgment, as it should be, the tone and general beauty of the untouched enlargement leave little to be desired.

COLLODION TRANSFERS—ENLARGED AND OTHERWISE.

It is a fact, in the history of photography, not a little odd, that many very excellent processes have been invented and published, which have either excited little attention and been quickly forgotten, or, having gained some attention, fail to make way with the majority, and soon fall into disuse. Many such processes might be named, amongst which we might classify the cyanotype process and its modifications, the ink process, in which a permanent image of gallate of iron is produced, the lac printing process, and many others.

Amongst these processes, producing excellent results, which have received less attention than they deserve, there is none more valuable than the collodion transfer process. The picture is exceedingly delicate and pleasing, presumably permanent, easily and rapidly produced, and generally gives satisfaction to the public. With existing facilities for rapid working, it is scarcely too much to say that on the dullest day in November a sitter might enter the studio, and within an hour receive a dozen completed eard portraits! This, of course, would be effected by the aid of gas or artificial light and collodion printing. The process originated by Dr. Moitessier received at first but little attention. Ultimately it was taken up by M. Disderi, and acquired considerable vogue for a time. After his collapse the process seemed to fall into disuse, and has remained so.

Its claims are various. As we have said, it is rapid, simple, and beautiful. A collodion film is, of course, much more delicate than paper. Every photographer has noticed with regret that his best paper prints fail to render all the delicate gradations to be found in the negative. The collodion print will give every gradation and detail the negative possesses. The print may be of the same size, or it may be larger or smaller, to suit any purpose. The process yields admirable enlargements, more rapidly than they can be produced by any other method. The printing can be effected by gas light, or even by lamp light. From the fact that we have repeatedly recently been solicited to re-publish instructions for working the process, we are led to conclude a want of knowledge of the process and its capacities is the chief cause why it is so little practised; we are induced, therefore, to give in the present number tolerably copious instructions for working this method, and applying it to various purposes, selecting the details from previously published articles by ourselves and others. We will subjoin here a summary of the working details and conditions required.

The Negative most suitable for this purpose is delicate, fully exposed, well defined, not intensified, and free from defects. A negative possessing sufficient vigour for printing

on albumenized paper is not suitable for this purpose. The kind of negative used for solar camera enlargements answers well. It is better unvarnished.

The Collodion should possess good body, and yield a tough film; a powdery collodion increases the difficulty of working. The proportion of soluble cotton will depend somewhat on circumstances; but, as a rule, not less than 6 grains per ounce should be used. Equal parts of ether and alcohol will answer for the solvents. Most good samples of bromo-iodised collodion will answer the purpose.

The Glass should be clean and free from scratches or defects. To facilitate the final transfer, its surface should be treated with a saturated solution of beeswax in ether, and then rubbed with a linen cloth.

The Nitrate Bath should be in good order for ordinary work, and be free from any disposition to fog. As a general rule, a new bath, or one which has been treated with cyanide of potassium, will give good results.

A Camera or Copying-box expressly for the purpose must be used. It will consist of a long box with a groove for the negative at one end, and a groove for the ground glass and dark shade at the other end. Midway is a sliding partition on which the lens is fixed. The box must be at least four times as long as the equivalent focus of the lens. If, for instance, the lens have an equivalent focus of 8 inches, the box must be 32 inches long. In operating, the negative should be placed so as to receive uninterrupted light from the sky, or a piece of white paper may be placed in such position as to reflect the light of the sky upon the negative. A stop, sufficiently small to give perfect definition all over, should be used in the lens.

The Developer may consist either of protosulphate of iron or pyrogallie acid. The tone of the print somewhat depends on the developer, and especially by the acid employed. The use of acetic acid tends to a brown tone; the use of citric acid to a blue-black tone; the use of tartaric acid also to a blue-black tone. The organico-iron developer possesses especial advantages in giving great brilliancy and aiding in the production of a black tone. Either of the following developers will give good results:—

Protosulphate of iron	5 grains
Citric acid	7 "
Glacial acetic acid... ..	10 minims
Water	1 ounce
Pyrogallie acid	3 to 6 grains
Citric acid	3 "
Glacial acetic acid... ..	20 minims
Water	1 ounce

For blue-black tones, a portion of the acetic acid may be replaced with tartaric acid.

The Exposure is an important element in securing good results. A full exposure and short development is best; if protracted development is required to bring out half-tone, the image is apt to be buried, and the picture looks dull, and lacks detail in the shadows. At the same time, it should be remembered that over-exposure and under-development tend to the production of an image lacking force and contrast. A little experience is the best guide.

The Tone of the Picture depends somewhat on the development; but after fixing (which may be effected with cyanide or hyposulphite of soda) and thorough washing, the picture may be toned with a neutral solution of chloride of gold, 1 grain to 3 ounces of water. The toning should be continued until the desired colour is seen at the opposite side of the film through the glass. Modified tones may be obtained by the known method of applying a 10-grain solution of bichloride of mercury, followed by a weak solution of sulphide of ammonium; but the film becomes tender after this operation, and renders the subsequent operation of transferring more troublesome. The time required for gold toning is very variable, according to the conditions of the print; it is much longer when the proof has taken a long time to develop, and is formed of intense blacks. It is seldom, however, that the complete action of

the gold bath requires more than three or four minutes; it often requires even less time. It is sometimes necessary to renew the toning solution once or twice; this happens especially when the picture possesses very opaque portions. The proof is finally washed in abundance of water, and it then only remains to transfer it to paper.

The *Transferring* is the most delicate operation, and requires the greatest manipular skill. The following is the method recommended by Dr. Moitessier:—After the last washing the plate is placed on a stand in a perfectly horizontal position; then pour over it as much distilled water as will remain, then apply to the film a piece of ordinary albumenized paper previously moistened, taking care that no bubbles of air are retained between the paper and the collodion; now raise up the plate, holding the paper by the two corners to prevent its sliding, and the whole is kept in a vertical position for a few moments, to allow the water to drain off. The plate is then left to itself until the paper is completely dry; it may be put in the sunshine, or brought near a fire to hasten the drying. Finally, the plate is immersed in a basin full of water, and, at the expiration of ten to fifteen minutes, the piece of paper detaches itself almost spontaneously, bringing with it the collodion film, which adheres to the paper in the most perfect manner. When dry the proof is extremely brilliant, and the most delicate details appear, with all the sharpness they possess in the negative.

In place of the albumenized paper here mentioned, an enamel paper, with a gelatinous surface, is especially prepared in France for this purpose, and is preferable to any other.

It sometimes happens that, from the under-exposure, the use of a too dense negative, or from the quality of the collodion, the transferred image looks less brilliant than it did on the glass before drying. To remedy this defect proceed as follows:—After toning and washing the finished collodion transparency, allow it to dry, and then varnish with a spirit varnish. When this is dry apply a thin solution of gelatine, containing a trace of glycerine or a little sugar. When dry apply a piece of the enamelled paper or plain paper, first dipped in water, as before described, taking care to avoid air-bubbles; when dry remove from the glass by inserting a penknife under the film. If the glass were properly treated with wax the picture will leave without difficulty.

In another column will be found an article on the production of card and other portraits.

PHOTOGRAPHY AND FORTUNE-TELLING.

A CURIOUS case, in which photography is charged as auxiliary to a system of false pretences and so-called fortune telling, was heard at Southwark Police Court a few days ago, a photograph of the "future husband" of applicants being sent for a number of penny stamps! The case is reported in our daily contemporary as follows:—

"Thomas Frederick Henry, described as a photographer at 42, Cooper's Road, Old Kent Road, was charged with pretending to be able to tell fortunes. Mr. Washington appeared for the prisoner. Sarah Weeks, middle-aged, said she was a widow, and resided at 1, Sandford Lane, Stoke Newington. At the end of last month she saw the following advertisement:—'Important.—Any unmarried persons sending their description, including date of birth and eighteen stamps, will receive in return a beautiful and artistic likeness of their future husband or wife, date of marriage, &c. Also my wonderful secret or fasmeter, carefully sealed. Address, T. Henry, 42, Cooper's Road, Old Kent Road, Camberwell.' On reading that advertisement she wrote a letter to the address, describing herself accurately, and enclosing eighteen stamps. A few days afterwards she received a packet from T. Henry, enclosing the photograph of a middle-aged good-looking gentle-

man, and setting forth that it was a likeness of her future husband, and that they would be married in less than nineteen weeks. There were also a number of papers relative to marriage, and some absurd and stupid paragraphs. Knowing Detective-Sergeant Wells, she communicated with him, and the present proceedings were taken. In cross-examination by Mr. Washington she said that she would not be disinclined to marry the original of the photograph if she liked him, and he was disengaged; but she was in no hurry. Sergeant Wells first called her attention to the advertisement, and asked her to write to the address, and he handed her the stamps required. She, however, wrote the letter and posted it herself. She described herself as a widow willing to get married. She had not been dissatisfied with the photograph, and had not written for the return of the stamps. John Wells, a detective sergeant of the M division, said that in consequence of numerous complaints reaching the Commissioners of Police relative to the advertisement, by direction of Chief-Inspector Fox, M division, he was instructed to make enquiries, and communicated with the last witness, who handed him the photograph and the papers received from the prisoner, whom he apprehended that morning on a warrant. On reading the letter to him, he said, "Oh, that's not much. It's under the Vagrancy Act." On searching his house he found a large number of photographs of ladies and gentlemen, papers, and letters (produced) similar to those sent to Mrs. Weeks. Inspector Fox here asked for a remand, inasmuch as he should be able to produce important evidence against the prisoner on a future day. Mr. Washington objected to a remand, as there was no evidence of fraud or deceit proved. The prisoner had sent a photograph which Mrs. Weeks approved. Mr. Slade said that if he (Mr. Washington) could bring the original of the photograph to marry Mrs. Weeks, that might alter his opinion. He remanded the prisoner for a week, and agreed to accept bail for his attendance."

ON A MODIFIED METHOD OF PREPARING GELATINO-BROMIDE EMULSIONS.

BY CAPTAIN ABNEY, R.E., F.R.S.

DURING a conversation with Lieut. Darwin, R.E., the Honorary Secretary of the Photographic Society, our thoughts turned to the gelatine plates with which at present most photographers are crazed. His remarks put me in mind of some old experiments I had made with collodion and gelatine emulsions before the advent of Mr. Bennett's process, and I determined to repeat them. The results I now communicate to your columns, as I believe they will aid the progress of gelatine emulsion making, by shortening the process of preparation. The method pursued, though not new in theory, is, I believe, new from a published and from a practical point of view; and it is certainly to be commended for its simplicity.

One of the great objects, I take it, in the preparation of a sensitive emulsion is to obtain it perfectly washed, that is, free from excess of soluble bromide, or free from soluble silver nitrate. In the latter case there is a general consensus of opinion that the elimination is incomplete when treated in the ordinary manner, since a portion combines with the gelatine, with a resulting production of red fog, &c. The most direct method of preparing silver bromide is by means of aqueous solutions of soluble bromide and silver nitrate, when the precipitate falls in dense masses of a curly nature. Why not use the direct method, since such a precipitate can be easily and rapidly washed? The general answer would be that the coarseness of the precipitate would interfere with the result. My answer is, however, try it, and see if it does. Let us suppose we want to prepare about 10 ounces of an emulsion with excess of silver, and that Bennett's formula is to be used. Weigh out 70 grains of (say) ammonium bromide, and dis-

solve it in 10 ounces of water, and add to it 1 drachm of nitric acid. To fully convert the 70 grains of bromide, we should require about 117 grains of silver nitrate, so weigh out 130 grains, and dissolve it in another 10 ounces of water. Pour the former into the latter gradually; whilst so doing stir well, and then allow the precipitate to settle. Pour off the supernatant fluid, fill up the vessel (a glass one by preference) containing the solution, stir well, and again pour off. Repeat this half-a-dozen times, or so long as blue litmus paper reddens in the decanted water. When the paper remains unchanged, drain off as close as possible, and wait for the next operation.

Whilst this washing takes place, the 200 grains of gelatine can be put into a bottle containing 9 ounces of water, and, when swollen, a gentle heat is applied till it is dissolved. The precipitated bromide is next spooned out into the gelatine solution, all particles being rinsed out with the warm solution. The bottle is next shaken up vigorously, and the would-be emulsion will look perfectly hopeless, coarse particles of the silver compound being distributed throughout the liquid. Place the bottle for a quarter of an hour in a pan of water heated up to 90°, and shake again, and pour out a drop on a glass plate. It will be found that a perfect emulsion is formed, smooth, and not very creamy. Coat a plate with this for trial, and keep the emulsion stewing as in Bennett's process. At the end of a day coat another plate, and stew again for another day; coat another plate, and so on as long as may be desired. It will be found that each day's stewing improves the sensitiveness, and that the colour of the emulsion dropped on a plate, when examined by transmitted light, changes from a dirty yellow colour, when first prepared, to a grey violet colour after several days' emulsification. Expose the trial plates, and note their increasing rapidity as the cooking is prolonged. One day's cooking or stewing will give one a decently rapid plate—as rapid, indeed, as a wet plate—and plenty of density. Are there any advantages with this method of preparation besides that of saving the washing? I think there are, as far as my limited experience with it goes.

I have not met with any of those plague spots (black or otherwise) of which Mr. Wainwright has so feelingly written. If this should prove to be the case, the cause of spots may be traced to the contact of silver nitrate with the gelatine, and the combination of the former with some impurity in the latter. At any rate, I have not met with any spots of any kind as yet, and I believe that the right point to aim at is to prevent the silver being *at all* in contact with the gelatine. It also appears to me that the physical quality of the gelatine is better by such prevention. Any sample of gelatine may probably be used, though, as to this, I cannot speak definitely.

The advantages of the method are, that an emulsion free from all soluble salts can be prepared in a couple of hours, since by increasing the temperature to 150° for a short time a creamy and sensitive state is produced.

REMOVING SALTS FROM EMULSION BY DIALYSIS.

A correspondent at Grenada, Mr. J. F. Gresham, makes the following suggestion:—

“Will you allow me to make a suggestion that may be

useful, at any rate, to the amateur portion of your subscribers.

Those who separate the water and soluble salts from their emulsion by dialysis would find a hurricane lamp chimney (globe or cylinder, or whatever it is called) very convenient. The rim round the top forms an excellent means of attaching the parchment paper, then by turning the glass upside down the emulsion can be poured in, and the operation proceeded with.—Yours very truly, J. F. GRESHAM.”

A NOTE ON THE PREPARATION OF SMALL QUANTITIES OF BROMO-GELATINE EMULSION.

BY T. SEBASTIAN DAVIS, F.C.S.*

In addition to the general application of photography to the wholesale production of pictures possessing commercial value, a special interest and greater variety is sometimes associated with the limited number obtained by enterprising amateurs. Means, therefore, to obtain such with facility, without the elaborate fittings desirable when a continuous supply of one particular kind is requisite, must at all times be desirable. Under this impression I venture to introduce to the notice of the Society an arrangement by which four or six ounces of a bromo-gelatine emulsion may be made and washed with great ease. Instead of using a ruby glass vessel, as usually adopted, I recommend for the preparation of the emulsion a well glazed rectangular or flattened bottle, made of stoneware. The solution of the gelatine and salts is effected when the bottle is standing upright; but when the whole is sufficiently digested, the emulsion is spread out into a thin layer by simply transferring the vessel to a horizontal position. When the gelatine is set, the plain stopper of the bottle is replaced by a cork carrying two tubes, one sufficiently long to reach to the bottom of the bottle for the inlet of water, and the other simply passing through its depth for egress. The outer portion of each tube may be advantageously bent into a spiral form so as to prevent access of light to the emulsion. A funnel being fastened to the extremity of the inlet, as long as water is allowed to flow into the same a current will pass over the preparation, and carry with it the soluble salts. When sufficiently washed the water can be drained off, and the emulsion, being redissolved by heat, will be ready to be filtered previous to its application to the plate.

In some preliminary experiments that I have made with the above I am led to the conclusion that no advantage is gained by first dissolving the bromide and silver salts before their addition to the emulsion. The bromide salt may, with less chance of loss, be directly added to the gelatine solution, and shortly afterwards powdered silver-nitrate in like manner. I may remark, in passing, as I deem my method to be now unusual, that in the analogous preparation of a colloid-bromide emulsion the direct addition of argentic-nitrate may be made, avoiding the necessity of the use of a hydrated alcohol, saving both trouble and loss, and giving an emulsion gradually formed with the silver-bromide in a fine state of division. The preparation of the gelato-bromide emulsion with the aid of the described apparatus can, it will be noticed, be made and washed, with the exception of the momentary interval of changing the corks, in ordinary light, and a minimum cost of trouble.

THE PHOTOGRAPHY OF VISION.

BY W. S. BIRD.*

THE daily and weekly journals occasionally indulge in quasi-scientific romances, and are prone to let imagination loose over photographic marvels. The latest tale of wonder has been concocted on very slender data in connection with recent researches on the physical structure of the retina, and with the endeavours to fix on that sensitive membrane the images that impinge upon it. The tale goes circumstan-

* Read before the Photographic Society of Great Britain.

tially to prove that upon the retina of a murdered person has been distinctly traced the photograph of the murderer and the theatre of the crime. Justice has been depicted armed with a new power for the detection of the criminal, and the old adage that "murder will out" has received a marvellous exemplification in the mechanism of the eye itself.

Belief in a story of this kind would not be difficult for many people, and even a photographer, knowing how parallel are the optical arrangements of the eye with the appliances of his art, would not be unduly credulous to give the matter some consideration. The eye and the ocular orbit, indeed, form a veritable camera-obscura, the dark lining of which necessary to absorb scattered rays of light is represented by the pigmented layers of the choroid membrane. The aqueous and vitreous humours answer to the lens, and serve the same optical purpose of collecting the rays of light to a focus, and throwing the image of external objects on the retina, which represents a concave sensitive plate. The iris, with its power of contraction and expansion, answers to the diaphragm, and the ciliary muscles, which change the curvature of the anterior surface of the crystalline lens to suit varying distances of the object from the eye, has its analogue in the adjusting screw. The parallel might be carried still further with considerations of optical aberrations in both the vital and the mechanical lenses, and the corresponding corrections by which in both cases the differences are compensated or modified.

Enough has, however, been said to show that it is not exceedingly strange if a ready credence has been given to accounts of images impressed on the living retina with uncommon vividness, being found there shortly after a violent death, and becoming a damning witness by the dead victim against the murderer. Fixing the photographic image thrown on a Daguerreotype plate was an almost miraculous fact at first, and that nature should be found more wonderful than art is an ordinary experience.

The intention of this paper is to indicate the small substratum of fact upon which imagination evolved its new romance, and to show the continued parallelism between the photographic and visual records of luminous impressions. The most recent researches of physiologists on the function of the retina bring the subject fairly in the limits of photographic interest. For the facts I shall bring before you I am largely indebted to an article in the *Revue de Deux Mondes* for March, entitled "Les Colorations de la Rétine et les Photographies dans l'Intérieur de l'Œil."

In the mechanism of vision the retina is the membrane that receives the image of objects, and conveys luminous impressions to the brain. A nervous current is believed to be set up by the impingement of the light, and we see; but by what transition a motion of nerve matter becomes a mental consciousness is a transcendent wonder, as much beyond the physiologist or the philosopher as it is outside our inquiry. But if in vital phenomena there is between means and the end a gulf impassable to our intelligence, yet all inquiry into the material basis of life leads to the conviction that vital manifestations are cognate with states and conditions of the organism, and researches into these conditions can never be a useless quest, although an ultimate mystery is involved that exceeds our power to solve.

The retina is a thin glossy membrane, the segment of a sphere, concave in front, and situated immediately behind the vitreous lens. Its texture is delicate, and its surface presents a small yellow spot, of which the centre corresponds with the anterior posterior axis of the ocular globe. This spot is believed to be the most sensitive portion of the membrane, and among mammals is found only in man and in the monkey.

Of old, anatomists saw in the retina only a membrane of two layers or coats, but in our days the microscope has largely augmented knowledge, and now some seven distinct layers are found, in one of which the presence of numerous minute cones and rods has been established, beyond doubt, by the concurrent testimony of independent observers. The

cones are mostly found in the yellow spot, the rods being more plentifully distributed throughout this coat of the membrane. These rods and cones, composed principally of extensions of the optic nerve, whose terminations form the anterior surface of the retina, have been likened to the papillæ of the skin in which the tactile nerves terminate. The cones are supposed to receive quantitative or colour impressions of light, while the rods take measure of intensity. Be this as it may, both cones and rods appear to play an important part in giving definite body to the image received by the retina. That is to say, the consciousness of seeing is not acquired merely by the image of an object falling on the retina, but the momentary fixation of that image takes place by physical changes in these rods and cones. It is this apparent fixing of the image which carries beyond previous experience the analogy of the globe of the eye and the camera.

The retina rests, as we know, immediately on the choroid membrane, which is full of pigment cells, the colour in which determines the hue of the external eye; but the substance of the retina, with the exception of the small yellow spot already mentioned, has, until recently, been considered colourless. The researches, however, of Professor Boll, of Rome, has led him to conclude that the true colour of the retina is purple-red, but that this colour is discharged by light. This visual purple can only be discerned in obscurity, or under such artificial illumination as will not discharge it. The colour does not disappear immediately with life, Professor Boll having preserved extirpated eyes for twenty-four hours, when the colour was still visible, and only disappeared on access of light. The cause of the retina having been hitherto found colourless is not, therefore, death, but it is simply the consequence of exposure to light. The retinae of rabbits and frogs which had been killed in the dark showed a bright purple-red colour, but if killed in sunlight the retinae were found colourless.

The existence of visual purple being thus placed beyond doubt, the quest began to discover its nature. Could it be a veritable pigment, or was it only a condition of physical variation in the structure of the organ? Freezing the retina did not destroy the colour, and while immersion in alcohol, ether, or chloroform, did destroy it, yet these liquids did not receive colouration. The existence of a pigment was doubted, but Kühne (a name well known among microscopic anatomists) succeeded in obtaining a solution of visual purple from which light expunged the colour. Kühne employed as solvent fresh bullock's bile, purified and freed from its own colour. He further collected the purple in powder, and found that while dry it resisted light, but if damp the light discoloured it. Putrefaction in its early stage did not destroy the colour. Solutions of the pigment were discoloured by solar light in a few seconds, by gaslight in half-an-hour. The extreme lines of the spectrum acted feebly, both red and violet; the blue and yellow were more active. The sum of Kühne's conclusions may be stated thus:—All visible light decomposed the retinal purple, but in variable times, the conditions of exposure being similar. Whatever the source of light employed, the visual purple, in losing its colour, passed first to yellow, then became white. The flame of sodium was found to be least active on the pigment, and experiments were conducted by this illumination.

In life, the colour of the retina renews itself continually; the source of the colour believed to be in pigmentary cells of the cones and rods mentioned as part of the structural apparatus of this membrane. The importance of this discovery of Boll and Kühne lies in the fact that here is seen for the first time palpable material modifications corresponding with impressions conveyed to the sensorium. This is a step forward in the mechanism of a conscious impression. The anatomy of the organs of sense has received the earnest attention of many eminent men, and the structures have been elaborately described without much insight into the functional method. Take the ear for an example: we are ignorant by what means a wave of sound impinging on the tympanum excites the nervous movement which results in

hearing. The impression must, judging by all analogy, be conveyed by some material means. If Boll be correct in his theory, he has in the case of vision gone a step further in discovery of the means, and the results may stimulate research on other organs. The theory is that the optical image thrown on the retina is momentarily fixed or apprehended by the actual formation of the pigmented picture in which purple corresponds to the shadows, white to the high lights, and insensible gradations between these extremes to the half-tones. This granted, we obtain wonderful insight into further correspondence between structural and conscious phenomena, and Boll goes so far as to say that the action of different agents, light and colour, waves of sound, palatable substances, odours, temperature, &c., produce in the terminal organs of sensation certain physical changes commensurate with the feelings produced. Such a statement touches in a revolutionary manner some old philosophies, but is in accord with similar tendencies of thought in various fields of research; still, it may be doubted if there be yet such firm foundation of fact as will support so bold an induction.

(To be continued.)

Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.*

The ordinary meeting was held at 5A, Pall Mall East, on Tuesday, May 13th, Mr. JAMES GLAISHER, F.R.S., in the chair.

The minutes of the last meeting having been read and confirmed,

The following gentlemen were unanimously elected members of the Society:—W. B. Bolton, 2, York Street, Covent Garden, W.C.; Captain R. Phelps, R.A., 58, Ennismore Gardens, Princes Gate, S.W.; A. Bisset Thom, 49, Torrington Square, W.C.; James John Walker, 133, Adelaide Road, N.W.; W. Willis, jun., 49, Palace Grove, Bromley, Kent.

A paper by Mr. Bennett was read by Lieut. Darwin "In Reply to the Papers Read at Last Meeting of the Society at the 'Discussion on Gelatine Emulsions' (page 255).

The reading of the paper having concluded,

The PRESIDENT remarked that from the length of the discussion which had already taken place on this subject, he might be expected now to close it. He would not do that, however, in case any gentleman had any remarks to make. They need not, of course, be very extensive.

Mr. FRY asked permission to add one or two words to what he had already said on this subject. Mr. Bennett, in his paper had noted that he (Mr. Fry) spoke with some confidence as to orange paper or glass being permissible in the dark room window. He might say, in regard to his remarks, that it was very dull weather at the time he made the experiments. Orange paper, with several thicknesses, did seem sufficient for the purpose, and give every security one could desire; but he found that as the actinic power was increased, he had to use ruby glass. On adopting ruby glass he found the protection complete, without any serious loss of light in the developing room. It was owing to the dull weather that he had found the results as he previously stated.

Mr. W. BEDFORD thought Mr. Bennett must have misunderstood what he had previously stated, as he merely put forward experiments he had made for what they were worth. He then compared three thicknesses of orange glass with one of ruby, and he found the orange was as good or better than the ruby. He could not withdraw, as Mr. Fry had done, what he had said—

Mr. FRY; I do not withdraw; I rather modify.

Mr. BEDFORD continuing, remarked that in practice it was inconvenient to employ many thicknesses of orange glass. If it was necessary to have two thicknesses of ruby, it would be equally necessary to have four or five thicknesses of orange glass. To his mind it was possible to manufacture glass which would be better for the eye than ruby, and equally efficacious. Mr. Bedford showed the result of an experiment which he had made since the last meeting, and remarked that it was suggested that he should try one thickness of ruby and one of stained red, against

three of orange. He had done so with the result that there was not much to choose between them. The great desideratum, it appeared to him, was to get glass of the proper colour and of one thickness.

The PRESIDENT read a letter from Mr. Nelson, in which that gentleman stated that a bronchial attack prevented his attendance to take part in the discussion upon gelatine.

Captain ABNEY stated that Mr. Bennett had rather misunderstood what he had said regarding fog on plates, and he could not well explain without a black board. Mr. Bennett stated that he preferred four square feet of ruby glass of four thicknesses, rather than one square foot of one thickness. In the latter case there would be at least sixty-four times more actinic light penetrating through the one thickness of ruby glass than if four thicknesses were used, as the penetration progressed in geometrical rather than arithmetical ratio. Four thicknesses should therefore be practically impervious to actinic light. The ruby glass he (Captain Abney) was going to refer to was made for him by a firm in Birmingham, and it was manufactured remarkably thin. He had the materials used for flashing made into sheets of the thickness of microscopic glass for a special purpose, and failed to distinguish the slightest trace of blue. Flashing, he thought, had something to do with the transmission of the blue. Mr. Bedford had referred to orange and ruby, and stained red. He (Captain Abney) would like to see Mr. Bedford's ruby glass, because there was ruby and ruby. [Glasses were here handed in and examined by the spectroscope.] Captain Abney remarked that there was a tinge of yellow going through the combination of stained red and ruby, and there was, as might be expected, of course, through the orange a large flood of green light.

Mr. BEDFORD; How do you account for the result?

Captain ABNEY did not know how it was, but it must be remembered that ordinary bromide emulsion was only sensitive as far as line B; there it stopped, because between B and C there was very little actinism whatever. There was another point, viz., with regard to local treatment of negatives, in which he did not agree with Mr. Bennett. In view of the importance of the correct arranging of light and shade, the gelatine process could never come into general use among artistic photographers if it was incapable of local treatment. He was only an amateur artist, but in the matter of light should not trust to any process which did not offer this facility. In a studio where the photographer had the control of curtains, no doubt gelatine plates ought to be perfect, because the portrait photographer had no business to work upon his negative during development: the effect ought to be produced in the original lighting. But when they came to landscapes, where it was not always possible for the photographer to choose his light, local treatment was highly desirable, and no process was perfect unless it was capable of such. Gelatine was rapid and good, but there was still the desideratum of being able to treat it locally, otherwise it would not come into general use amongst landscape photographers.

Mr. T. S. DAVIS then read "A Note on the Preparation of Small Quantities of Bromo-gelatin Emulsion" (see page 260).

Colonel WORTLEY remarked that, since the last meeting, he had made experiments in reference to one of the points mentioned by Mr. Cobb, of Woolwich, viz., the negatives changing colour in the light after intensifying. His (Colonel Wortley's) plates were exceedingly hard; in fact, he desiccated them thoroughly. He had exposed one of the plates to the sunlight ever since the last meeting, and there had been no change in it whatever. Whenever there had been any sun the plate had been subject to its influences, but there had been absolutely no change. Certain plates had been sent to him which he found had not been perfectly desiccated, underwent the same ordeal with the result that they were much stained. They were all stained in a peculiar manner, no matter how thoroughly they were washed, after they had been in the light. That being the case, he purposely took a plate which had not been thoroughly dried—half of it being more or less desiccated, and the other portion only surface dried; and having developed it in the same way as the others, the result was that there appeared a red stain conspicuously in the portion which was not dried, and he even found a large crystal embedded in the film itself, which resisted all possible washing, so firm a hold of it had the gelatine got. There was another point to which he would direct attention. Several persons had complained of the appearance of red stains on their negatives, a peculiar circumstance which was described in the *British Journal* as red and

* Condensed from the Official Report.

green, with which he was familiar under certain circumstances. Three weeks ago he prepared emulsion with the greatest possible care, there being ten plates wherewith to carry out the experiment. In the result he found that nine of the plates developed perfectly, and gave as good negatives as one could wish to see, but the tenth came out with the yellow and green stains in all their hideousness. He had always considered it a great mistake to omit the bromide in the developer, and the plate he referred to was the only one in which bromide was not used. If bromide and pyro were washed over the negative before adding ammonia it was nearly impossible to produce the stains. To show the necessity of thoroughly washing before fixing as well as after, he exhibited to the meeting a sample of the hyposulphite bath in which only some half dozen plates had been immersed. [*The liquid shown was of a deep red.*] He impressed strongly upon all who made gelatine plates the necessity of thoroughly desiccating the plates. It was, he believed, the solution of all the evils which people complained of. His own plates were almost like glass; and it would be almost as difficult to scratch them as glass.

Mr. S. DAVIS: Will Colonel Wortley describe his method for drying?

Colonel WORTLEY: It is what I first recommended—the use of alcohol.

Captain ABNEY added, that he found in fixing plates that a certain amount of sulphuretted hydrogen was given off, but what the cause of it was he was not prepared to say.

The PRESIDENT, in closing the discussion, said they were all exceedingly indebted to the several experimenters who had so kindly given the members the result of their labour. He might say if the desiccation of the plates was so important as Colonel Wortley stated, that gentleman might, at some future time, tell them how to obtain such complete desiccation.

Votes of thanks was then accorded to the various speakers.

The PRESIDENT then read the following letter from Mr. Dallmeyer:

“19, Bloomsbury Street, London, May 13th.

“DEAR SIR,—I regret my inability to be present at the Society's meeting this evening. I therefore send you what I intended to bring, viz., a complete series of Mr. Muybridge's wonderful instantaneous photographs of trotting horses, kindly sent me by that gentleman. The sight of these pictures will, I doubt not, be as interesting to the members of our Society as it has been to men of science, artists, &c., throughout Europe and America.

“I venture to think that this novel application of the art has a great future. Certainly, Mr. Muybridge, of the “far West,” deserves all credit for the skill and enterprise with which he has accomplished so difficult a task.

“As will be observed, each picture bears its own explanatory remarks upon the mount; and in regard to the modus operandi of their production, I cannot do better than give it in Mr. Muybridge's own words. He says:—

“I decided upon the “Patent Stereographic” for several reasons.

“1st. They have a much greater depth of focus than either the No. 2 or No. 3 B (of which I have a pair of each), and will permit the horse a greater latitude in his track; I therefore thought that although the C lenses might work much quicker, there would be great danger of their being out of focus, through the horse not being kept on the plane intended.

“2ndly. My shutters are constructed on this plan—

represented at the instant of their respective openings passing the lens. They are drawn up and down respectively by means of powerful rubber springs, released at the same instant by the action of an electric battery. I found by experiment there was a limit to the width of the opening, in order to obtain a photograph of the horse without apparent movement, and I could not advisedly use a width to permit a full exposure of a much larger lens than the “Patent Stereographic.” I might be enabled to use the No. 3 C by having an entire new set of shutters made, but think I shall be enabled to obtain good detail—even with brown or bay horses—by the use of an emulsion I am now experimenting

with, employing the “Patent Stereographic” lenses. I think I have now about 65 or 70 of them.’ I am, dear Sir, yours i thfully,
J. H. DALLMEYER.”

The prints accompanying the letter having been passed round for inspection, Mr. BIRD read a paper on “The Photography of Vision” (see page 260).

The PRESIDENT asked if any of the members were desirous of speaking. There being none, he added that he hoped Mr. Bird would keep his eyes open, and keep the Society well informed of any similarly interesting features in visual photography.

After a vote of thanks and some other proceedings,

Mr. YORK exhibited an instantaneous shutter, which was examined by the President and members. The principle of the shutter was the dropping of a metal plate through an aperture pierced in the tube of the lens, as suggested by Capt. Abney, in front of the diaphragm. Mr. York claimed for his shutter an instantaneous exposure combined with freedom from vibration.

The PRESIDENT expressed the pleasure of the meeting at the presence of Mr. Mauners Gordon. He hoped that, as the discussion paper for the next meeting was not filled up, some gentlemen would see their way to introduce some matters of interest.

Mr. GORDON replied to the remarks of the President, and said he was excessively glad to find himself once more among them.

The meeting then stood adjourned till June 10th.

PHOTOGRAPHIC SOCIETY OF VIENNA.

An ordinary meeting of the Society took place on the 1st April Dr. E. HORNG in the chair.

After the transaction of the routine business,

The CHAIRMAN drew the attention of the members present to a collection of eight views of the fall of an avalanche at Bleiberg, sent for exhibition by Herr A. Beer, and took advantage of the opportunity to make some remarks on the great importance of photography in criminal and judicial inquiries. More especially, he pointed out that the most skillful draughtsman is unable to depict, with complete accuracy, alterations and injuries due to natural causes in the very short time during which they often remain stationary. He also referred to the arrangement adopted in France, by which photographs are used to give a correct idea of the condition and progress of building and engineering works; also in the Prefecture of the Police in Paris, where not only portraits of criminals are carefully preserved, but photographs are also taken of the prominent objects and localities illustrating the occurrence of accidents and crimes. These are often of more service than the most carefully drawn up oral or written evidence. The president further expressed a wish that the Government of Austria might, in the interest of the public service, avail itself of the aid of photography as well for administrative and judicial purposes, as in scientific investigations.

The SECRETARY read a paper by Herr A. Ott, of Hottingen, near Zurich, on the employment of photo-lithographic transfer papers. In this paper the author first gave a short historical sketch of his subject, and then pointed out some defects to which the preparation of these papers are subject, concluding with a description of a method for producing them, in which the danger of altering their dimensions and shape is avoided.

A paper by Dr. J. Seiffert, of Tupham, was read by the CHAIRMAN, on the value of the radiometer for photographic purposes. After a number of experiments conducted both by himself and other investigators, the author maintained, in opposition to the commonly received opinion to be gathered from various text books and manuals, that the instrument is only of importance for thermometric purposes, and can in no way be used as a photometer or actinometer.

Herr SCOLEK described the instantaneous process of Krob, which had been mentioned at the last meeting, and gave an account of its successful results. It depended essentially, first on the preparation of the collodion, and secondly in the employment of two developing liquids, one for the general image, the other for the details.

Herr LUCKHARDT explained that he as well as Herr Angerer had received on trial a supply of gelatine emulsion and some dry plates prepared by Herr Obernetter, of Munich; the sensitiveness of these plates is so great that it is impossible to work with them in ordinary dark rooms without fogging. Herr Obernetter has produced plates that only require 1-20th part of the exposure to which wet plates must be subjected, and ordinarily sends out to his friends and customers plates which are five times as sensitive as the collodion plates in common use. The speaker pointed out the great advantage offered to portrait photographers by

using plates of this extreme sensitiveness, particularly in the taking of groups and children. He also complained of the inexcusable carelessness of the Custom House officers, who paid no attention to the label on the lid of the box containing the plates. The terms of the direction expressly warned against the box being opened anywhere but in the dark; but, not content with disobeying this instruction, they had even removed the tinfoil wrappers from each plate, to ascertain the net weight.

Dr. HORNIG referred to his remarks at a former meeting on this danger in importing dry plates. He explained that when a large number of plates were ordered, arrangements could be made for the Custom House officers to examine the packages at the house of the importer, though this plan would be too expensive in the case of small orders. Similar complaints had been raised at Berlin, and in one case a successful attempt had been made to resensitize plates that had been submitted to similar treatment.

Herr ANGERER stated that he had himself fetched his plates from the Custom House, and in this way had been able to arrange for the whole package to be weighed without breaking bulk. He exhibited the plates which he had exposed at 4:30 p.m., one for five, the other for fifteen seconds; both were fully exposed photographs, the latter only much more intense. With wet collodion he would have been compelled to expose for forty-five seconds at the same hour. In his dark room, in consequence of observing signs of fogging on the first plate that he attempted to take, he had been obliged partly to cover the windows with a curtain, partly to provide the panes with a second layer of yellow paper. The speaker expressed the very high opinion he entertained of these plates, and pointed out the many advantages they offered, especially in taking views of interiors and groups.

Herr HAACK reported on his experiments with the plates sent by Motter, of Amsterdam. He confirmed the statement that they only required one-half the ordinary exposure, but could not observe that they manifested a greater sensitiveness for yellow objects. The negatives were developed strictly according to the instructions of Herr Motter, but turned out rather weak.

Herr ANGERER preferred the brown tone of the Obernetter plates to the blue-grey tone of those of Motter.

The PRESIDENT pointed out that as far back as 1874 he had drawn attention to some of the advantages of gelatine emulsion. Unfortunately, no member of the Society (with the exception of Herr Haack) had taken up the subject, while in England the improvement of the process had been diligently worked at, and now for some time gelatine dry plates and dry gelatine emulsion had been produced on a commercial scale in that country. He expressed a hope that the results now brought before the meeting would cause the gelatine emulsion process to be more actively studied.

Talk in the Studio.

PHOTOGRAPHIC EXHIBITION.—An exhibition of photographs will be held at 5A, Pall Mall East, in October, by the Photographic Society of Great Britain. Further particulars will be duly announced.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The last meeting of this Society before the recess will take place on Thursday next, June 5th, at the Society of Arts, Adelphi, at 8 p.m., when papers will be read by Mr. Brittlebank and the Honorary Secretary.

PORTRAITURE BY ELECTRIC LIGHT.—His Royal Highness the Prince of Wales one day last week honoured Mr. Vanderweyde with a sitting for a portrait by the electric light, and expressed much interest in the arrangements.

REMARKABLE PHENOMENON.—A remarkable occurrence with reference to the photographing of a church weather-cock at Tenby is reported. At the time nothing was observed by the artist but the object upon which he was engaged; but on the development of the plate the outline of a boat, with colours flying fore and aft, was distinctly visible about two-thirds up the spire, in a reverse position. The photograph was taken at a quarter past six, and about that time the gunboats were launched at Pembroke Dock. It is thought that it is a mirage of one of the gunboats soon after launching.—*Lancet*, May 24, 1879.

To Correspondents.

SCOPTICON.—The popular edition of the Autotype Manual is to be obtained of the Autotype Company, 36, Rathbone Place, London, W. The price is one shilling. Between the two lenses you mention there is not much difference in performance. They are both excellent.

HOWARD.—The lens you describe is undoubtedly a landscape lens. When sent out by the maker it would have a cap or cover fitting the end. This has, doubtless, been lost. You can make another of cardboard or pasted strips of paper. The small tube is a step to regulate the aperture.

C.—We cannot tell whether the picture is copyright or not, as we know nothing of the circumstances. It may not be safe to copy it; but it is quite safe to leave it alone, and right, besides. It is illegal to put the word "copyright" or "registered" on a picture which is not so. The demands on our time do not permit us to answer questions by post which are addressed to the Editor.

J. BERENGER.—We regret very much that we never have such leisure as you imagine. Our engagements fill the whole of our time, and often leave us in arrears. You will find some good information on the subject in Lake Price's book on photography. You will not find it convenient to have the dark room exposed to the full glare of the sun in summer.

R. G. D.—The portable tourist camera which we devised for our own use, and described some years ago, was made by Mr. Meagher. We do not, as a rule, commend the work of special makers in this column; but the manufacture of the camera to which we refer was excellent and very satisfactory to us.

HYDROGEN.—We hope to give full particulars of the portrait illumination by gas-light, in our next, as employed by Mr. Laws, whose studio we visited for the purpose of seeing the arrangement.

G. G. F.—In all the negative processes, that is, the methods of producing negatives, salts of silver are employed. No other substance has yet proved sufficiently sensitive for camera images. Negatives may easily be reproduced on carbon tissue, and with great advantage. But the field for experiment in discovering a new method of producing negatives lies open to all comers still!

TYRO.—If carefully performed, the method of precipitating the silver from an old bath by means of zinc answers very well. Place the solution in a jar, and immerse a strip of thoroughly cleaned zinc, which should be long enough to project above the jar, and so be easily lifted to stir with, and so hasten the operation. After it has remained for twenty or thirty hours, test the solution by the addition of a pinch of salt. If this causes no turbidity, it may be concluded that all the silver is thrown down. Pour off the supernatant water, and wash the precipitate very thoroughly. Then place in an evaporating dish, and pour on nitric acid. By the aid of gentle heat the precipitated silver will be converted into nitrate. After the nitric acid has been evaporated by continued application of heat, the nitrate of silver may either be fused, or washed and recrystallized.

ANXIOUS.—The change in the pictures produced by the dusting-on process suggests that the bichromate is not perfectly removed. The best practice is, we believe, after developing the image by the powder, to wash with a saturated solution of borax in spirit. Then dry, and afterwards immerse in dilute nitric acid. Finally, wash well with water until all bichromate is removed. After being properly washed, the picture should not alter at all. Much personal skill and care are required to succeed thoroughly with the process.

B. Y.—If the gelatine plates are properly managed, sufficient density should be obtained in the development. If that have not been effected, then you may thoroughly wash the plate, and intensify with acid pyro and silver; or, better still, with a solution of iodide of mercury. 2. You may try the usual methods of reducing intensity, but it is matter for experiment. It is easy to avoid the necessity. 3. Photographs are registered at Stationers' Hall.

P. C.—The most recent works on portraiture, &c., are the two by Mr. Heighway, published at the Office of the PHOTOGRAPHIC NEWS.

PYRO.—You cannot very well show gelatine negatives as positives. In our opinion the best system is to receive the money before sitting; but unless the system be thoroughly and properly carried out it is sometimes difficult to manage. If persons sit and receive proofs and then take no further notice, you can recover in the County Court. In some cases we have known a magic lantern system is kept in order ready to show a portrait on the screen as soon as it is taken. There are so many considerations to be taken into account that no general rule can be laid down, still less can any efficient advice be given in the space limited to answers to correspondents.

R. BRGOS.—Many thanks. Several Correspondents in our next.

The Photographic News, June 6, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHING A MIRAGE—M. JANSEN'S OBSERVATIONS AND OBSERVATORY AT MEUDON.

Photographing a Mirage.—The *Lancet* records an instance of photographing a mirage. It appears there was a desire on the part of a Tenby photographer to secure a picture of the tower and weathercock on Tenby church. The photograph was attempted in the evening at a quarter past six, when at this season of the year there would be ample light for the purpose. When the plate came to be developed, there appeared upon it, about two-thirds of the way up the spire, the distinct outline of a vessel with colours flying, but in a reversed position. Tenby is rather more than ten miles from Pembroke Dock, it seems, and about the time in question there happened to be a launch of a gunboat, on which occasion, as everybody knows, a good deal of bunting is displayed. The explanation offered, therefore, is that the reverse image secured upon the photographer's plate at Tenby was the reflection of this gun-boat at Pembroke Dock against clouds, or evening mist, which was sufficiently luminous to show the image. It would be interesting indeed if this were confirmed. There is little doubt that a mirage that can be appreciated by the eye is quite capable of being photographed, but we should like to have better proof that this has been done at Tenby. Several ways occur to photographers whereby such a result as that detailed in the *Lancet* could be secured, the simplest being that the plate employed was an old one, and had previously been impressed by the image of a vessel. That this was reversed in the spire picture of course goes for nothing, since the plate might have been employed the other way up when previously used. We all know how to make ghost pictures by securing glass plates upon which a former image has been so vigorously developed as to be positively etched upon the surface of the glass. Something of the same kind may possibly have happened in the case of the Tenby picture, and as the photographer had doubtless many times before occupied himself in the depiction of shipping, it is not very difficult of belief that he may have got an old plate etched with an old image. At the same time, as we pointed out not very long ago in these columns, the photographing of a mirage should not be difficult, where the scene is plain to the naked eye. The Dover mirage of 1876, which we have before referred to, might certainly have been depicted in the camera if the happy thought had occurred to anybody to make the experiment. On this occasion—a very hot afternoon—the town of Boulogne opposite was distinctly seen represented in a mirage. Boulogne is thirty miles distant from Dover, and yet the dome of the cathedral, and that other well-known landmark, Napoleon's Pillar, as likewise the Crescent Walk, were all visible to the naked eye. With the aid of a telescope it was possible to see the entrance of the port, the lighthouse, the shipping, and surrounding houses. The adjacent coast would likewise be traced in the mirage, the formidable Cape Grizney, with its lighthouse, together with several villages and farms in the vicinity. Some of the houses, we are told, towards evening had their windows lit up by the declining sun, and stood out with extraordinary clearness, while at one time a locomotive was seen to leave Boulogne and travel some distance in the direction of Calais, its track being marked by puffs and wreaths of white smoke. If a mirage can be seen as distinctly as this—and the Dover phenomenon is only one out of many on record—there should be no reason why the ghostly picture could not be secured upon a collodion film. Still we should desire an opportunity of inspecting the Tenby mirage photograph before pinning our faith to its authenticity, since it is the first instance on

record, we believe, of photography having made record of such a phenomenon.

M. Janssen's Observations and Observatory at Meudon.—M. Janssen is still working hard at his interesting solar observatory at Meudon. Gradually, but surely, he is perfecting his method of observing the sun by photography. M. Janssen stands alone in his researches in solar photography. For the past ten years he has devoted himself almost entirely to the subject, and his reward has been that he is appointed chief of the observatory at Meudon, where he has at his disposal some of the finest instruments in existence. M. Janssen's last important discovery was, as our readers may remember, the fact that when a picture is taken of the sun with the briefest exposure, there is a vast amount of important detail to be seen. In some portion of the surface the sun appears covered with round granules; in others, these are comet-shaped or elongated, implying motion. The picture in this instance was secured by an exposure of $\frac{1}{5000}$ of a second, and the result having been so satisfactory, M. Janssen now proposes to work only with very brief exposures. New apparatus is being constructed for the purpose, which will permit exposures being regularly made at intervals of two minutes, or for something like $\frac{1}{2000}$ of a second, the pictures of the solar disc, without enlargement, measuring not less than fifty centimetres. This leaves our own observatories at Kew and Greenwich far behind; and if we desire to learn anything of the physical character of the sun, we must in future go to Paris for M. Janssen's results. He still employs his *revolver* apparatus, which he first used at the Transit of Venus operations, and the successive views obtained within two minutes of each other have already given valuable results. In a word, it is found that two images of the sun taken with but a short interval of this character between them differ materially from one another. The phenomena which we have chosen to designate as spots, change, apparently, much more rapidly than is supposed, and within two minutes a couple of pictures of the sun may be secured that by no means resemble each other. Thus we have ample proof that changes are for ever going on in the sun, and there seems little doubt but that M. Janssen will very shortly be able to tell us something more of these changes through his constant watchfulness with the camera. The palace of Meudon, with its park, a lovely suburb of Paris, was, our readers may remember, almost destroyed during the last Franco-German war, and when M. Janssen was permitted to occupy the spot with the instruments that he had carried to Japan and brought back again after they had served to observe the transit of Venus, the chateau was a mere shell with scarcely more than the walls standing. M. Janssen's investigations have, however, turned out so well, and appear to be so full of promise, that the French Government has now decided to build him a structure fit for an observatory, with telescopes and cameras furnished with the latest improvements. When he has the benefit of these improvements we may look to the energetic French photo-astronomer for further interesting results of his work.

THE PHOTOGRAPHY OF VISION.

BY W. S. BIRD.*

THE existence of visual purple, and its special relation to light acknowledged, the more ardent investigators fancied photography discovered, and concluded that by supplying conditions which should temporarily fix the image on the retina, incontrovertible evidence might be obtained of the fact. It was not unreasonable to suppose that a visual image strongly impressed on the retina, and materialised in actual pigment, would remain there sufficiently long to record its own evidence. If so, such evidence in cases of violent death by accident or crime would indeed be conclusive and

* Continued from p. 262.

minister to justice. To solve the problem was difficult, for the vital action which furnished continual supplies of colour to the retina and the decolouring effect of light were compensatory. To obtain an optograph it was necessary this compensation should cease. Various experiments were made; Kühne had satisfied himself that while the visual purple was not immediately destroyed by death, yet that the power of renewing it was obliterated, and the conclusion followed that to fix an image on the retina long enough to prove his theory, he must still follow photographic practice and cap the vital lens immediately after exposure. Not only must he thus secure the sensitive retina from further access of light, but also stay the vital compensating action by destroying the life. But before arriving at this double conclusion, he experimented with the freshly extirpated eyes of rabbits, fixed these immovably for a few seconds before a brilliantly illuminated object, then shut out the solar light and examined the retina by the sodium flame. The results were unsatisfactory; for although the form and relative site of the object were discernible on the retina, the outlines were too vague and indeterminate to convince the doubtful. Kühne attributed this partial failure to the opacity both of the cornea and of the retina which death produces. Light would be hindered in its passage through the eye to the retina, and that membrane probably lowered in sensitiveness. He, therefore, sought to overcome the obstacle by experimenting on the living animal, which he placed before a square opening cut in a window shutter; the creature's head was first covered with a black cloth to ensure full development of the visual purple, then the light was allowed to act for a couple of seconds, and the animal immediately decapitated. One eye rapidly extirpated by the light of a sodium flame was plunged into a solution of alum, and the other eye left in its orbit similarly treated. Next morning, the two retinæ were detached, and there was distinctly visible in each the square image representing the luminous opening, and more accentuated in the second eye than in the first. Upon exposure to light, the image disappeared by the decolouration of the whole retina. Thus encouraged, Kühne undertook to photograph more complicated objects, and succeeded with rabbits, under the conditions described, in obtaining perfectly distinct impressions of a window; not merely the square opening, but the vertical and horizontal bars were distinctly visible. He succeeded thus far equally with eyes in a recently decapitated head, but the exposure in such case was much longer than when the experiment was conducted with the living animal. The difficulties of such inquiries were, of course, very great, but Kühne believes not merely that optography is an established fact, but that it is possible to obtain landscapes and portraits photographed on the retina, when the conditions can be brought under greater control.

Something must be allowed for the enthusiasm of the discoverer, but the ascertained facts are sufficiently striking to give probability to the theory, and remarkable enough to account for the romantic statements which have had some currency in the newspapers. The facts are strange, for it is almost inconceivable how any mechanism of the sort can adjust itself to the varying experiences of one minute's vision. The rapidity of the impressions received, their constant succession, the variety of objects far and near discerned in a single glance are so immense, that it is bewildering to believe that every gradation of light and shade registers itself in the minute structure of a delicate membrane, by waves of purple colour momentarily modified in harmonious correspondence with the impact of reflected light! The retina becomes the microcosm man has been said to be, and that we are fearfully and wonderfully made may be better realized now than in the old time. This marvellous adaptation of means to an end is paralleled by the modification of the curvature of the anterior lens of the eye to enable us to focus distance. For sharp definition in the camera, either the lens or the sensitive plate must be shifted for different planes of distance, and a similar adjustment is necessary in the eye.

From any distance exceeding seventy yards, rays of light entering the eye may practically be considered parallel, and no adjustment is required; but between these seventy yards and four inches, which is the average point of proximity to the eye for an object to be clearly seen, there must be adjustment. If we look through the meshes of a net at an object beyond it, both cannot be clearly seen at the same moment. In the interval by which the two objects are discerned, the ciliary muscles act to increase or diminish the curvature of the front surface of the lens. Conceive the almost instantaneous rapidity with which we discern objects scattered over a distance of fifty yards, and yet at every point of the distance each object distinctly seen was focussed on the retina by a distinct change of curvature of the visual lens! One reason why viewing a picture or sculpture gallery is so much more fatiguing to the eye than continual change of landscape, is, that in the one case there is perpetual action of the ciliary muscles to accommodate the varying convergence of the rays of light, while in the other the parallelism of the rays makes no such demands on the organ. It is as wonderful a power of accommodation to optical necessities, and as marvellous in itself, as the colour changes in the retina for the performance of its function.

Without venturing to express an individual opinion on the discoveries and theories of Boll and Kühne, but willing to wait for further confirmation, I have thought a statement of these latest novelties in vital optics worthy the attention of the members of this Society.

COLLODIO-BROMIDE WITH GUM GUAIAUCUM.

CAPTAIN ABNEY, writing to the Society's Journal, says:—

"The members of the Society are invited to try a modification of the ordinary washed emulsion process, as it is believed that it is valuable in more ways than one. The modification consists in adding to the washed emulsion one-sixth part of alcohol which has been saturated with gum guaiacum. The plate is coated in the ordinary manner, and the film takes a greenish blue tint when dry. The drying may be done 'spontaneously,' or it may be accelerated by the warmth of a drying room or box; but the temperature should not exceed 120°, since the gum then fuses, and the film repels the developer. Those plague spots that refuse to develop have not been found to be present except in one or two plates, and the fact of their presence has been recognised before placing them in the dark slides, since they remain of the ordinary colour of the bromide whilst the surrounding portions are coloured as stated above. It is something to be able to see the spots before development, and on this account alone the addition of this gum is valuable. To develop, the plate is flooded with alcohol, and then washed and treated with the alkaline or ferrous oxalate developer in the usual manner. The film, being very porous through the removal of the gum, readily takes any amount of density, and it is amenable to intensification with pyrogallie acid and silver nitrate. If a phantom image be developed first by a weak developer, it may be built up as the operator may choose. The film has no tendency whatever to leave the plate; even the most horny film becomes glued to the surface, and, as before stated, easily permeable to the developing solutions.

"The gum acts as a preservative, as will be seen by the simple experiment of dissolving it in alcohol, and pouring the solution over a clean plate. On evaporation of the alcohol, a hard transparent film is left. The keeping qualities of these plates between exposure and development have yet to be tested. If they keep as well after exposure as they do before, they will be very useful plates for the tourist. The writer appeals to photographers to try the process, in the hope that it may lead by experiment to the introduction of a really good preservative which may be applied to the plate with the emulsion itself. Gum ammoniacum has been already used by Mr. Stillman, but

its comparative insolubility is a great drawback to its use as a preservative. Gum guaiacum combines with bromide, hence it is efficient on this score.

AN EXPERIMENT WITH ORANGE PEA-GREEN COLOUR FOR STUDIOS.

MR. COCKING, in the *Photographic Journal*, says:—

"Whatever the scientific explanation may be, it is nevertheless a startling fact that if the unglazed parts of our photographic studios are coloured orange pea-green, certain results follow which were not present when coloured with the hitherto orthodox blue tint. Having only recently painted my own studio with this orange pea-green colour, I record a few effects which have forced themselves upon my notice.

"Upon the *sitter*, the effect was one of pleasantness, inducing vivacity, both of look and bearing, inducing the remark, 'How bright and cheerful the studio looks!'

"Upon the *photographer* (in addition to the same facts as experienced by the *sitter*) the effect was that of increased power of perception, by enabling him to estimate the amount of red colour in the faces of sitters, and thereby assisting in the calculation of the necessary duration of sittings.

"Upon the *sensitized plate* the effect was also very marked, inasmuch as the general exposures were shortened considerably; and in one instance a *sitter*, with a full amount of red colour in the face, was taken with about half the exposure in presence of the orange green colour, which three days before was required in presence of the old blue colour. Also in this case another very important fact was observed, viz., that the resulting negative was much smoother on the face, requiring but a minimum of retouching as compared with the negative taken with the blue colour in the studio.

"The materials I used were white lead, ultramarine blue, lemon chrome, and orange chrome, as procured at the ordinary oil shops. The tint, that of the green pea pod when the sun acting upon it just takes away the purity of its original green colour, and imparts a slight orange tint.

"It remains for *time* to show whether *light* acts upon this peculiar colour, and, consequently, whether the results are maintained or not."

THE "NEW DEPARTURE"—ITS THEORY AND PRACTICE.

BY J. TRAILL TAYLOR.*

WITH a considerable amount of gratification have I observed that at least one gentleman has had the enterprise and courage to make a "departure" from the well-worn routine that prevails in portrait galleries.

In the number of the *Bulletin* for January last, Mr. D. N. Carvalho describes the steps by which he was led to discard the time-honoured and orthodox blue colour so long peculiar to the interiors of photographic studios (or skylights), and to substitute therefor a colour which may fittingly be designated a very pale pea green, this being attended by a remarkable reduction in the time required for exposure. The reduction is alleged to be in the ratio of fifteen seconds to thirty or forty seconds. This represents a gain of so important a nature as to warrant us in bestowing upon it a more than ordinary share of attention.

Before proceeding to offer some remarks both of a theoretical and practical nature upon this subject, I may state that in the practical part of the subject—the advantage to be derived from the use of such a colour—my views are quite in accordance with those of Mr. Carvalho, but I am unable to accept the theories upon which his deductions are based. However, "not to put the cart before the horse," I shall

first of all discuss the theory upon which our views are likely to clash, and then proceed to the practical bearings of the subject, on which we shall doubtless find ourselves in entire harmony.

The following is a digest of the theory advanced by Mr. Carvalho:—A wine-glass, if filled with a transparent blue liquid and interposed in the path of a ray of light, transmits that ray not of a blue, but of an orange colour, as proved by its shadow being received upon a sheet of white paper; that the principle of changing the colour of the ray is not confined to transmission through a coloured medium, but also acts by reflection; for example, a blue reflector causes the emergent light to be complementary to the colour of the reflector, or orange, and so forth with regard to other colours. This being the case, if it be desired to secure a beam of reflected light of any particular colour, it is only necessary to ascertain the complementary colour to that required, and make the mirror or reflector of that hue. An orange coloured reflector does not, according to this theory, reflect orange, but blue, which is the opposite of, or complement to, that colour. In like manner a blue reflector projects an orange beam; with a red reflector, green will be reflected. Having settled the theory, Mr. Carvalho deduced this conclusion—that seeing it is desirable to have a violet light upon the *sitter* in the studio, the surroundings must be of the colour complementary to violet, namely, a yellowish green; and by painting the studio this colour a great degree of rapidity is obtained consequent upon the flood of violet light which thus falls upon the *sitter*. This is the theory of the "new departure," as far as I am able to understand it from the letter of Mr. Carvalho, and I now proceed to show cause why it is not likely to be accepted by physicists.

When light is reflected or radiated from a matt white surface, such as a white card, the different coloured rays are reflected in the proportion to constitute white light. This is an axiom of universal acceptance, as also its antithesis, that if light falls upon a body that entirely absorbs it, such body does not reflect light, and consequently appears black. But equally axiomatic is it that if light falls upon a coloured body which does not entirely absorb it, there is always some reflection of white light and of light of the same tint as that of the absorbing body; the reflected rays would be white light, if to them were added those which were absorbed by the coloured body, and the one set of rays, the reflected, are complementary to the others which have been absorbed. An opaque reflector of any definite colour absorbs the colours complementary to that of itself and reflects only the latter. Thus blue reflectors reflect blue rays; so with yellow, green, red, and other colours.

This is also the case with transmitted light; by means of blue glass window panes we flood the room with blue light, and if we wish to exclude from our dark-room those rays which act detrimentally upon our sensitive plates, we admit only orange or ruby rays, which we do through orange or ruby glass. Although Mr. Carvalho found that the wine-glass filled with blue liquid cast an orange shadow upon the sheet of white paper, he would have found that by employing a glass bath having parallel sides as the medium for holding the fluid, the beam of light transmitted, or the shadow, was of precisely the same colour as the fluid through which the light was transmitted. So with coloured glass or transparent paper. If we wish a room to be illuminated with yellow light, we employ yellow glass; and in order to secure the maximum of illumination with the minimum of chemical action upon our sensitive surfaces, we admit the light into our dark rooms through a medium of the same colour as the light we wish admitted. If Mr. Carvalho's theory were correct, of two glass caps for the lens, one fitted with violet and the other with orange glass, the latter would transmit more actinic light than the former. But in practice the opposite is the case. From the foregoing considerations will be found my reasons for dissenting from the theory of the "new departure," as given by Mr. Carvalho.

But when we discard theory and come to practice, I am entirely at one with this gentleman. The colour which he

* *Anthony's Photographic Bulletin*.

finds so advantageously to supplant the time-honoured blue paint of the studio is a delicate pea green. So far from being unpleasant to the sense of sight, the eye rests upon it with a far greater feeling of satisfaction than it does upon the cold blue or grey so redolent of the studio interior. I am not aware of the methods made use of by the Messrs. Anthony in compounding this pigment, which is sold in convenient cans ready for use after dilution, but a good idea of it may be had from making a mixture of the pigments so well known as deep chrome and Prussian blue. Now this forms a mixture that radiates a large amount of what has been termed actinic light. A proof of this is to be found in the fact that if a piece of cloth this colour be affixed to a larger piece of a blue colour, and both be photographed together, the greater density of the green in the resulting negative clearly shows that it reflected more actinic light than the blue which served as its background. The physiological fact that it is more grateful to the eye, added to the chemical fact that it reflects a large amount of chemically active light, entirely prove the utility of the new colour as one which may much more fittingly than blue be used with excellent effect as a coating for the wall of the studio.

To anyone who would affirm that this is contrary to true theory, I would reply—not so. Our ideas concerning actinism have undergone quite a revolution since Robert Hunt, in years now long gone by, promulgated his theories concerning the chemical action of certain colours of the spectrum. In the old days of the Talbotype—or Calotype—iodized paper, the iodized Daguerrotype plate, or the iodized collodion with its pyrogallic development, there was much force in the remark that the photo colourific value of blue was white, while that of deep yellow, orange, or red was black. But this notion received a death-blow by the introduction of bromine and the bromides, by which the yellows, reds, and blues have assumed a more accurate position in the scale of colorific representation.

From an experiment I made last summer in the Orkneys, I discovered that the rays emitted by the setting sun in these latitudes were devoid of photo-chemical power to a singular extent. These rays beat fiercely upon one side of the face of a gentleman whom I was photographing in a garden, and when the image was examined upon the focussing-screen of the camera the opposite side was in deep shadow. But when the image was developed no trace of the predominating action of the solar light could be seen, but, on the contrary, the opposite side of the face, which was visually the darker, showed as if it had been the better lighted of the two.

This subject is an interesting one, and Mr. Carvalho deserves thanks for bringing it forward for discussion.

POSING THE SUBJECT.

BY O. W. OSBORN.*

IN my communication which appeared in the March number of the *Practical Photographer*, I there mentioned that I would give a few hints on various subjects connected with photography. So, seeing that nearly everything was pretty well written up, except lighting and posing, and as the former was treated of in last month's issue, I conclude that a few remarks on the above-named subject would not be out of place.

In the general make-up of all pictures, whether they be portraits or landscapes, it should be the aim of the photographer to secure the appearance of solidity as much as the nature of the subject will admit. This very desirable quality is produced by two methods: first, by so arranging the subject that the picture, when completed, shall not appear top-heavy. As an illustration, we will take a full-length picture of a young lady. It is presumed everything is in order under the skylight, so we will direct the lady to assume her position under the same. Take the high-back posing chair, and move it around to within a few

feet of the side light, but far enough away to allow your subject to be placed on the side next the light, without coming closer than about six or seven feet to it. Now turn the body of your subject around, so that if she was looking straight ahead, her eyes would be directed to a point on the wall about opposite the end of the light farthest from the subject; adjust the chair so that the young lady may rest one or both arms on it, as your taste may dictate; always have the back of the chair lowered sufficiently to allow the subject to lean slightly thereon. Take a piece of yellow paper, the size of a sheet of commercial note, and place it in your subject's hands, and direct her to assume the appearance of having received a letter from some friend, while you place a neat little piece of paper on the chair seat to resemble an envelope, and also place a little stand or table of some kind on the side of the picture nearest to the light; throw some part of the drapery over the back of the chair, and let one end of it fall gracefully to the floor on the side of the chair farthest from the subject. Place a vase of flowers or a small piece of statuary on the little stand. Now see that there are no ugly folds or other obnoxious things to be seen, and, after having elongated the lower extremity of the lady's dress, so as it will not appear too compact, you may adjust the curtains of the sky and side lights so they will do their duty, and not let in a flood of uncontrollable light. You may make the exposure, being careful to give time enough; for more of delicacy and roundness depends on that one operation than a great many are inclined to believe.

The reason I have gone so much into the details of the above, is because so many are careless, and even if they have those little things, such as draperies, chairs, and tables, which add so much to the beauty of a picture, and which are the only assistants in securing pyramidal composition with single figures, may seem too diffident to use them.

Now suppose we had not used the accessories above, but, instead, had placed the lady in a common chair, with her face fronting the instrument, and had placed that characteristic old book in her hand, and had used no fine interior background with the light falling gracefully through an opening in a cottage window, but used the old ground elevated five or six inches from the floor, and have had made her a picture after that style, with the entire sky and side light thrown wide open, which do you suppose she would take, provided she had her choice? I venture the assertion that she would not take the last one, no, not even if you would offer to throw in another book just to balance the picture, you know. Of course, some one will say, could not this person have been posed after some other manner, and still have got good pictures? Yes, certainly, a variety of ways, and have them all good, too. She could, of course, have been treated to a sitting posture, with one arm leaning easily and gracefully on the back of the chair; or to an old style bust; or, better still, a vignette Rembrandt, provided she was not too lean to make a nice shadow picture; or to any other style, provided the photographer kept everything in harmony, and observed the laws of gravity, one of which is, that any leaning object, which it is intended to represent as being solid or firm in its position, must be provided with something visible in the picture to serve as a support. Take any picture where the subject is represented as leaning upon an object of some kind for a support, and remove that object, no matter what it is, and your subject immediately has the appearance of falling. I repeat, that if the laws of gravity and pyramidal composition be observed, there will not be much difficulty in securing good and artistic pictures, at least so far as the posing is concerned. Not long since I had the pleasure—if such it might be called—of seeing a photograph made by one of those peculiar kind of photographers who know too much about the picture business to take any photographic

* Continued from page 226.

journal, which was enough to make a stair laugh. It represented a young lady standing by a high-back chair with one arm resting on the same, which was all well enough; but the operator, not knowing what to do with the other arm, concluded to get up something peculiarly fine, so a happy idea entered his noddle, and he thrust a very conspicuous jardiniere stand into the composition, but unfortunately on the wrong side of the subject, for he put it by the side of the large chair, and between the chair and the instrument, and so far away that the lady was compelled to lean forward considerably in order to be able to barely rest her fingers on the edge of the stand. You see how ludicrous such an arrangement would appear, with all the accessories on one side of the subject, and nothing but blank space on the other side. Such violations of all art principles are, I am sorry to say, only too common. If Sarony had been posing that subject, he would have placed that stand on the other side of the picture, or have left it out entirely. In portraits of elderly persons, and especially of the male portion of humanity, it is best not to give too much animation to the subject. They should as a general thing be turned somewhat away from the light, and the head and body should be made to face in nearly the same direction, but not rigidly so, as some latitude is always allowable, and therefore the body could be turned from the instrument so as to give a three-quarter view, while the face could be turned a little more toward the instrument, and the eyes be made to follow in the same direction, being turned still a little more than the head. Of course this must not be exaggerated, for then all the solemnity of age would be destroyed, and the vivacity of youth substituted in its stead. Always allow the eyes to be turned a little, and I may say but very little, more in the same direction in which the head is turned. Nothing could be worse than to see this rule reversed, and observe the head turned in one direction and the eyes in the opposite direction. If the head is turned to the right, it suggests the idea that something is attracting the attention of the person in that direction, and, as a matter of course, the eyes should certainly follow in the same direction.

In some cases it is the artist's intention to avoid the appearance of pyramidal composition, and so the order of things is reversed; the most noted illustration of which is the celebrated picture by Thorwaldsen, called "Night," and represents an angel floating in the atmosphere, bearing in her arms two infants, "Sleep" and "Death." Here, as I said before, all idea of such composition is lost as the lines drawn from the extremities of the wings to the feet of the principal figure would represent an inverted pyramid. I have seen in simple bust portraits such gross violation of art principles, that a word or two on that point may not prove unwelcome. Now it seems as though the merest tyro ought to be able to pose a person for a bust picture; and yet, even simple as it is, many forget one of the most important things, and that is, the direction of the eyes. They will pose the body and the head as they should be, perhaps the body turned a little toward the light and the head somewhat away from it, and when ready to expose the plate, will tell the sitter to "look right into the instrument," forgetting, as it were, that such a direction of the eyes in connection with a position similar to the above is productive of anything but a first-class picture. Of course, such oversights as indicated above are not of every day occurrence, but that they do occur once in a while cannot be denied. It may be that they are caused by a rush of business, but if such is the case, I would advise that they be reduced to the smallest number possible; for it is a fact, that negligence and oversights of that kind are very good advertisements for the gallery across the way. I will again urge the importance of closely scrutinizing the sitter just before making the expose, for by so doing you avoid a great many re-sittings.

ENLARGEMENTS ON CANVAS BY TRANSFER.

This process is simple and excellent, and is the most efficient mode we know of obtaining an image on canvas, and, being a transfer method, all the risk of imperfect fixation or imperfect washing which attends the method of printing on canvas direct is avoided.

The collodion must possess a good body. If it be prepared expressly for this operation, it should not possess less than ten or twelve grains of pyroxyline to each ounce of solvents. A good commercial sample of bromo-iodized collodion may be used, to each ounce of which five or six grains of pyroxyline—or, rather, we believe, papyroxyline—are added. Any of the known modes of producing a good positive image on collodion may be employed: those methods described as suitable for photo-crayons, with pyrogallic acid development and gold toning, will be found the most efficient of any.

The prepared canvas, as sold ready for the painter, is employed. The somewhat greasy and repellent or waterproof surface requires first of all to be removed. This is effected by means of a warm solution of common carbonate of soda, applied with a piece of flannel. After well scouring with this solution until clean water flows freely over the surface, it is thoroughly well rinsed, and allowed to dry. The glazed surface of the prepared canvas will now have acquired a matt surface of slightly absorbent character. This is then treated with a weak warm solution of gelatine, containing from ten to twenty grains to an ounce of water, applied with a sponge, and suffered to dry. The canvas prepared in this way may be kept ready for use.

The collodion enlargement, having been fixed, toned, and washed, is now placed on a levelling-stand, and a strong solution of citric acid in water—the exact strength is unimportant, say thirty grains to an ounce—is poured over it, and allowed to remain a few minutes. The action of the citric acid is two-fold: it restores the toughness of the film, which has become somewhat powdery in character from the action of the mercurial solution; and it loosens the film from the glass. After a few minutes the citric acid solution is poured off the plate, and preserved for subsequent use. The film is now very thoroughly washed under a tap for five or ten minutes, during which time it will have become completely loosened from the glass, upon which it will readily slide about. Should it not become loose during the washing, it must be again treated with the citric acid solution, and again washed. If a tardiness to loosen be noticed, the edge of the film may be lifted, and a gentle stream of water suffered to run underneath.

A sheet of tracing-paper the size of the plate is now taken and placed upon the film. If two persons can be engaged in the operation, some little trouble in subsequent operations will be saved, if the tracing-paper is first wet and suffered to expand; each person then taking hold of two corners, the tracing-paper is gently laid upon the film. If one person only is engaged in the operation, the tracing-paper is more easily managed dry in the first instance, as there is less difficulty in handling it so as to get it down flat on the film when a large plate is used. One edge of the collodion film is then turned over the tracing-paper, and the whole, paper and film adhering, lifted by a sliding motion off the glass, and placed, film down, on the prepared canvas. It is then covered with blotting-paper, and thoroughly well rubbed down; the tracing-paper—which has simply served as an aid to lifting the film, and, by its transparency, permitted the position of the image to be seen in placing it on the canvas—is then lifted away, and the transferred film left to dry.

When dry, this film adheres so perfectly to the prepared canvas that it cannot even be scraped away without injuring the surface of the canvas. It cannot be removed without scouring with hot water or a hot solution of soda.

The head and such other portions of the figure as may be desirable can be thus transferred to the canvas, and such other portions as may be required can easily be painted in by the artist.

The Photographic News.

PORTRAITURE BY GAS LIGHT.

The advance of summer naturally quenches much of the interest in the subject of portraiture by artificial light which has prevailed amongst photographers during the last few months. But it may be as well, as the subject has recently excited attention, to put on record a few more facts and observations on the subject. By far the most important step, in our estimation, which has been taken in this direction is the application by Mr. Laws, of Newcastle-on-Tyne, of ordinary gas light for producing portraits. So important did we regard the matter, that we visited Newcastle for the express purpose of seeing the light and examining Mr. Law's arrangements for employing it, in order to give our readers the benefit of full information on the subject.

There is an odd tendency amongst mankind frequently to seek for a remote and complicated agency to effect that which might easily be achieved by a simple and familiar appliance. Photographers have, for many years, tried various unfamiliar, and some troublesome, sources of artificial light for use in their art, whilst common gas, always at hand, easily applied, not costly, has been totally overlooked. To Mr. Laws occurred the happy inspiration, on witnessing the trials of some superior gas burners, to try their availability in photography, the result being marvellously successful. He now has established in his studio, as a portion of his regular appliances, one of Wigham's large gas burners, by the aid of which he is enabled to produce excellent portraits, independent of sunlight, in fifteen seconds, practically little more time than is required in ordinary daylight for similar work. At first sight it would seem that ordinary gas, with its comparatively dull non-actinic flame, was peculiarly ill-suited for photographic purposes; but it must be borne in mind that by the aid of the burner employed there is not only a much greater body of flame, but a much higher quality of light obtained. The quality of the gas is not, as might be naturally supposed, modified by naphthalizing, or charging it with additional carbon, but the flame is rendered more intense by means of more perfect combustion. The burner employed by Mr. Laws consists of sixty-eight jets, or fish-tail burners. These jets are packed together as close as possible, side by side. They are contained in the base of a hollow truncated cone, resembling, in size and proportions, the lower half of a sugar loaf; the diameter of the bottom about eight inches, of the top about six inches. All the jets being simultaneously lighted form a large intense conical flame; suspended about ten inches above the burner is a tube or chimney of tale about six inches in diameter, towards which the flame is drawn, and within which apparently all the products of combustion are absolutely burnt, adding considerably to the intensity of

the light. The theory upon which the intensity of the light obtained is based will perhaps be best explained by an extract from a paper read by Mr. Wigham before the British Association at Dublin, where he described the application of gas to lighthouse illumination. He says:—

"It occurred to me that if any plan could be devised by which the excess of carbon—the smoke—existing in rich gas flames could be turned to account as a means of increasing their illuminating power, a valuable desideratum would be obtained. I accordingly made many experiments with that object, and came to the conclusion that I could find no better basis for my efforts to that end than the ordinary well known fish-tail jet. The fish-tail jet, it is hardly necessary to say, is bored diagonally on opposite sides of a small internal cone. The streams of gas issuing from the orifices impinge against each other with considerable force, and the result is the thin sheet of flame with which we are so familiar. This flame possessing a large surface, to which the oxygen of the air readily gains access, is in consequence rendered brilliant and comparatively smokeless. But on closely examining the flame of a fish-tail burner it will be seen that towards the top, where the force of the stream of gas is nearly expended, it is thicker and inclined to be smoky. The larger the bore of the burner the thicker the stream of gas, and (its pressure and quality being good) the greater the amount of unconsumed carbon. When a number of fish-tails are arranged so that the upper extremities of their flames touch each other, they run up (because of the absence of air between each jet) into very smoky tails; but the light they give when thus united is increased (with hardly any increased consumption of gas) much beyond the mere multiple of their single flames, as may be seen in a moment by bringing two fish-tails together. I made this peculiarity of the fish-tail available for producing a large flame of highly illuminating power, and I devised this form of burner. I used in its construction double jets, by which a more effective combustion of gas is attained with less consumption for each jet than in the burners which I used in my earlier experiments. The principle of the double jet is not new, but I believe that the present form of its application is entirely so. It is exceedingly simple, and may be explained by this ordinary gas burner.

"It will be seen that the power of this burner is obtained not only by the peculiar arrangement of numerous fish-tail jets, but by suspending over the flame which they unitedly produce an oxidiser of talc or other material by means of which a current of air is brought in contact with its most smoky part, rendering it not only smokeless, but exceedingly white. The combustion is also assisted by a bottom cone for equalising the current of air to the flame. The oxygen of the air is thus twice availed of, first, at the bottom of the flame, through the medium of the several fish-tail burners; and secondly, at the top of it, where its action raises to a white heat the large quantity of solid carbon found there. This may be seen if I light this burner, which is one of the ordinary clear-weather lighthouse burners, and show it to you without, and with, its oxidiser. I may say, in passing, that burners like this are superior to any form of argand burner in this important particular, that they require no chimney glasses, the breaking and cleansing of which often cause much inconvenience in lighthouse maintenance, to say nothing of their presenting an obstruction to the passage of the light of the flame to the dioptric apparatus."

Mr. Law's burner is fixed on a standard about five feet high, the sitter being placed about six or eight feet distant. Of course reflectors play an important part in utilizing gas light for purposes of portraiture, and Mr. Law has adapted very simple but efficient reflectors. Over the light itself, Mr. Law uses a concave reflector such as he found already existing in commerce. It is like a large saucer (twenty-seven inches diameter) lined with strips of silvered glass. A hole in the centre allows it to hang over the chimney, adjusted at a suitable angle for throwing the light on the sitter. This practi-

cally gives the top light. A smaller one of eleven inches diameter is placed so as to give side light, and a similar one, a little more in front, lights the front of the face sufficiently. An ordinary swing dressing glass is found sufficient for giving reflected light on the shadowed side of the face. The reflectors referred to, cost, we learn from Mr. Law, something under thirty shillings. Whilst we are referring to the question of cost, we may mention that details on such subjects may be learnt from Edmundson and Co., 19, Great George Street, Westminster, who erected those now to be seen on Westminster Bridge.

As the full combustion is only necessary during the actual exposure, the cost of gas is reduced to the fraction of a penny. The portraits produced by Mr. Laws are for the most part very excellent. Some were a little heavy in the shadows, but many were indistinguishable from ordinary daylight pictures.

There is ample room, we think, for experiment with gas improved by some of the methods which have been proposed for securing a whiter and intenser flame without increasing its volume. In the Royal Observatory at Greenwich a gas-flame reflected by a mirror which reflects the deflections of a needle, indicating the variations of the magnetic currents, provides a photographic record of the magnetic variations during every twenty-four hours; and in this case, if our memory serve us aright, the flame is derived from naphthalized gas, which gives a sufficiently actinic flame to produce the record. This is a point upon which the President of the Photographic Society of Great Britain can give some information.

Mr. Wm. Brooks, of Reigate, an ardent experimentalist and exceedingly skilful practical photographer, has produced some good photographs of dark caves by the aid of paraffin lamps only. Possibly increase of number of lamps or excellence of burners might render paraffin sufficiently powerful for portraiture. The introduction of the rapid gelatine plates, peculiarly sensitive to those rays which have been usually regarded as almost entirely non-actinic, has introduced new possibilities into the art, of which photographers will not be slow to avail themselves.

FRENCH CORRESPONDENCE.

THE REAL STATE OF THE QUESTION OF THE REPRODUCTION OF NATURAL COLOURS BY MEANS OF PHOTOGRAPHY.

As I am still absent from Paris, and am living at my family residence in the neighbourhood of Marseilles, it is scarcely possible for me to find the materials for an interesting letter on photographic subjects. Even if I were in Paris, I should experience some difficulty in bringing anything novel or important to the notice of the readers of the PHOTOGRAPHIC NEWS, so few and trivial have been the occurrences in our photographic world during the past fortnight. I may, therefore, be permitted to give the present letter rather the character of a discourse on some of those principles and incidents of our art with which I am more familiar.

Occupying, as I do, my leisure by reading the various photographic journals that are sent to me from all parts of the world, I have had occasion to observe that the question of the reproduction of natural colours by means of photography is one which is generally not sufficiently understood. With regard to the important and interesting researches of M. Ch. Cros and of M. Ducos du Hauron, I have many times seen the expression, "Reproduction of natural colours." Now, this title, as it seems to me, cannot with any truth be applied to the investigations of which I am speaking, though it is far from my intention to criticise them or to depreciate their value. All that I am anxious for is that the real state of the case may be accurately comprehended, and I therefore take it on myself to explain how it is that these processes, in which the public is apt to believe that there will be found a means of taking natural colours, are in

reality nothing but highly artificial methods of producing polychromatic pictures by means of photography, and that there is no pretence for supposing that a coloured facsimile of the original can be obtained with any high degree of certainty and exactness.

Every fascinating theory has the effect of carrying away the minds of those who do not give themselves the trouble of examining it fundamentally, and I have myself observed distinguished *savants* to be so enraptured with M. Cros' views as to believe that they contain the solution of the problem of the reproduction of natural colours by photography. If I am not mistaken, this is the opinion of the learned M. Radau himself, who has put it on record, in his recently published and excellent work entitled, "Photography and its Scientific Applications." In a number of articles which I have studied, their authors come to the same conclusion, one which, in my opinion, is formed under the influence of an illusion spring from the very natural wish to obtain the solution of this cardinal problem of photographic science. Already, on many occasions, I have had no hesitation in expressing this opinion—a perfectly loyal and disinterested one—for, so far as I myself am concerned, I have never had the least pretention of obtaining natural colours. Being, therefore, myself completely outside the dispute, I retain the perfect liberty of judging impartially, and that is why I make use of it.

What strikes me at once, on examining more closely the theory of the above-mentioned investigation of this subject, is the principle which they assume that by means of red, yellow, and blue, we can obtain all the other colours of the solar spectrum. It is a fact that violet, green, indigo, and orange can be obtained from these three primary colours, and hence the conclusion that all the colours of nature can be obtained from the red, the yellow, and the blue. But, in my humble opinion, this conclusion is an erroneous one; for there are in nature a multitude of tints *sui generis* which are not the resultants of a forced combination of the colours of the solar spectrum. There are, moreover, black and white, which are not found at all in the spectrum, besides the metallic effects which are not represented in the light of the sun.

What I have thus stated is incontestable; it is not a question of theory, but of facts whose evidence cannot be denied. What becomes, then, of the theory of the complementary colours in the application of colours to photography? It reduces itself to this: the possibility of obtaining by means of three negatives with red, yellow, and blue, a polychromatic reproduction of an object coloured by nature, whose colouration would be the absolute resultant of the single combination with each other of the seven colours of the solar spectrum. Besides, this reproduction, to be quite true and artistic, would involve the necessity of employing a fourth negative, giving the colouring and modelling of the shadows which the three above mentioned colours are unable to realise alone. Evidently the three negatives obtained by filtering the light through violet, green, and orange glasses or media, even supposing that the selection of the red, yellow, and blue rays has been effected with mathematical accuracy, can only give a picture modelled, indeed, throughout, but, owing either to free colour, or to the different proportions of the three colours employed, wanting in an essential particular—the colour of the shadow; this is a species of grey depending neither on the red, nor the yellow, nor the blue. Black will be approximately rendered in those parts where the superposition of three colours of an intense quality will give a very sombre hue; but if we lower gradually each of the colours which form this sombre hue so as to approach nearer and nearer to a colour which becomes clearer and clearer, we shall not arrive at the result of obtaining first the pure tint of the shaded object, nor afterwards the grey which expresses exactly the hue of the shadow. From this point of view I have carefully examined the most successful prints of M. Ducos du

Hauron, and I have failed in finding the peculiar tint of shadow.

There can be no doubt that I have avoided mentioning a host of minor difficulties, such as the requirement of producing three negatives, of which one is taken by light that has passed through an orange medium; or, again, the impossibility of finding three pigments which in a state of powder shall be the equivalents of the red, the yellow, and the blue of the light of the sun; in this respect tinctures would be preferable to powders, for the rays of the spectrum are combined in penetrating matter in a liquid state, and are not superposed in distinct layers. It is true that the luminous rays passing through blue and yellow media placed over one another produce green, whereas projected separately on a screen, and then caused to combine in one projection on the same screen, they produce white. The question, it will be seen, is an exceedingly complicated one, but it is necessary from theory to derive a practice which, though it may not be capable of adoption on a large scale, shall at least satisfy the conditions of the reproduction of natural colours.

The most that can be said with strict regard to the truth of the processes proposed to us is, that by means of them we can succeed in obtaining polychromatic photographs, which, though they cannot be compared to the original object as regards colour, produce, at any rate, an harmonious effect and one agreeable to the eye—just like those chromo-lithographs printed with three colours only, which, considering the small number of colours employed, are very pleasing to look at. To complete the photographic process of the three negatives, it would be necessary to make it still more complicated: in the first place, a fourth negative would have to be added in order to render the relative values of the hues of nature, and to give modelling and colour to the shadows; and in the second place, it would be requisite to produce, by artificial means, either all the other tints which the three primary colours combined among themselves could not furnish, or those metallic hues which cannot be obtained from red, yellow, and blue. Thus it will be seen there is still much remaining to be done to perfect the process, and that, too, with the further condition that the difficulties of working, which are already so great, must on no account be increased; even then a method of printing so mechanical as this is hardly deserves the name of natural. Nothing, in my opinion, is less natural, and for this reason the working of such a process commercially can never be a success except for fancy pictures; it will never be employed for the accurate reproduction either of works of art, or of scientific originals. Before giving way to a desire to enter on any particular road, we ought to be quite certain whither it will lead us. Now, in the case before us, we do not see how the subject treated in the way that has been indicated can possibly bring us to the desired result. MM. Cros and Ducos du Hauron are no doubt persevering, as it behoves all investigators to be, and there cannot be the slightest doubt but that they are working in perfect good faith; they have been pursuing the same path now for a very long time; but what the state of the question was eight or nine years ago the same it is to-day. The improvements in the details have in no way modified the error in principle. Greater delicacy in the prints, methods for obtaining the negatives more rapidly, better separation of the distinctly coloured rays, are all so many steps in advance which may have a useful application for another purpose, but they will not lead us to the end we have now in view. So long as the arrangements at the point of departure remain defective, the results obtained at the goal can never be true. To anyone who, in inquiring about these processes, shall use the words, "Natural colours!" we must reply, with all the strength of conviction, No! and a thousand times, No! The reproduction of colours as they are in nature is the prize in a competition still open to all the world, and blessed will be he who shall make the wonderful discovery.

LEON VIDAL.

DRY PLATE EXPERIENCE. THE PLATINUM PROCESS. PAPIER ARTIGUES, ETC.

BY CAPTAIN WATERHOUSE.

[We select the following interesting experiences from a letter just received from Captain Waterhouse.]

Of photographic news I am afraid I have but little to give you.

I noticed that the writer of "Photography In and Out of the Studio" a few weeks back expressed a wish that I would give the results of my experience with dry plates. I have not worked very much with them except when preparing for the transit of Venus. The process I like best and have found most sure in working is the coffee process as given by Mr. Whitehouse in the YEAR-BOOK for 1877, and I am just now about to prepare some plates for use in Afghanistan by it. I have taken such plates with me from Calcutta to Singapore and back, and to Darjeeling, and have found them to do well. I have lately tried developing coffee plates with ferrous oxalate developer, and found it answer well, though it seemed to require longer exposure than alkaline pyro. Further trial is, however, requisite before I can speak confidently on this point. It is only now and then that I can get out to try a plate. Emulsion plates would do well here too, though I have not had time to work that branch out. I have obtained very good results by a modification of Canon Beechey's process, using coffee or tincture of anatto as preservative. Beer and pyro did not answer so well in my hands.

I have been working Willis' platinum printing process, and am much pleased with it. The keeping powers of the sensitized paper, the rapidity of the exposure and development, and the extreme cleanliness and simplicity of the manipulations, make it most useful in an office working short and limited hours, besides its other intrinsic advantages.

I see in the News for April 4th, just received, a notice of some "Papier Artigues" for copying drawings, plans, &c." Some of your readers may be interested in knowing that a very fair substitute for this paper may be made by brushing over Rives paper with a thickish mixture of glue and Indian ink, so as to leave a thin and not too highly coloured coating.

It is sensitized by floating, back downwards, on a solution of bichromate of potash, and, after exposure to light, washed off in cold water. I find it very useful for producing copies of maps when only a few copies are required. It is, however, only suitable for the same class of subjects as photo-zincography—i.e., those drawn in clear black lines, and not shaded. Glue works better than gum or albumen, and is quite sufficiently soluble in cold water. Mouth glue is very good. Gelatine is good also, but requires hot water in washing off.

Some years ago Mr. Swan prepared for me some paper for the same purpose, which answered very well, though I did not follow up the process then. The paper could no doubt be very easily prepared in large quantities by the Autotype Company or other makers of pigment tissue. The paper should be hard, and unabsorbent. Rive paper seems to give the cleanest results.

While on this subject, I may mention that trials of Mr. Pellet's cyanifer paper, prepared according to his formula with oxalic acid and perchloride of iron, and developed in a solution of yellow prussiate of potash, which is said to produce prints exactly similar to the original—i.e., prints with dark lines on a clear ground, from an ordinary pen-and-ink drawing—gave me exactly opposite results, and it was only by developing with the red prussiate that I obtained the stated results; but with this developer there was such a tendency to reversed action that the process seemed to be of little practical use as it stood, and I had not time, nor was it worth my while, working out modifications. If any of your readers have tried the method, I shall be glad to know their experience.

OFFICIAL REPORT OF PHOTOGRAPHY AT THE ROYAL CORNWALL POLYTECHNIC SOCIETY, 1878.

SECTION I. PROFESSIONAL.—SECTION II. AMATEUR.
JUDGES:—Messrs. T. Hart, Chairman; W. N. Carne.

THE Judges have great pleasure in bearing testimony to the great advance made in their department during the past twelve months, and to the exceedingly high character of many of the exhibits. The rules of art in form, composition, light and shade, &c., seem to have been studied to good purpose by some of the photographers, and the consequence is that in many of their works there is a marvellous perfection which ministers to our noblest gratification. The Judges hail with pleasure all those who are trying to lift photography out of the mechanical abyss, where it has too long remained, into a higher and purer sphere, and feel that they recognize, with their brothers of the brush, that the essence of the art is spiritual.

Section I.—PROFESSIONAL PHOTOGRAPHY.

1. For the best landscape, size not less than 14 inches by 11 inches, a first silver medal has been awarded to E. Forhead, Ventnor, for his fine view of "Old Church, Bonehureh," No. 604.

2. For the best landscape, size not less 11 inches by 9 inches, a first bronze medal to Marsh Bros., Henley-on-Thames, for their view in Quarry Wood, near Great Marlow, No. 619.

3. For the best landscape by the collodion emulsion process, size not less than 9 inches by 7 inches, first silver medal to W. England, for his splendid Swiss view, No. 666. Mr. England exhibits fifteen gems (views in Switzerland), all in his well-known style, possessing the highest artistic excellence—full of atmosphere—broad, yet exquisite in detail.

4. For the best interior by any process, size not less than 11 inches by 9 inches, a first silver medal to A. J. W. Penn, India, for his fine Indian Interior, No. 684.

5. For the best portrait taken direct, size not less than 14 inches by 11 inches, a first silver medal to W. M. Harrison, Falmouth, for his fine study, "Portrait of a Boy" (untouched), No. 638. This is more like a photograph from an "Old Master" than a study from life. It is full of artistic feeling, soft in outline where it ought to be, and the lines just strong enough where required, and all subservient to the face. It is a photographic triumph, reminding one of the "studies" seen in Rome and Florence.

6. For the best portrait, size not less than 10 inches by 8 inches, a first bronze medal to Robert Slingsby, for his Portrait of a Lady, No. 650. This is a very fine study beautifully modelled, well lighted, and very soft; one of the finest portraits in the collection from an artistic point of view.

7. For the best group, composition or otherwise, size not less than 14 inches by 11 inches, a first silver medal to Messrs. Chaffin and Sons, for their group "Cheekmated," No. 614. This is a very fine composition, though the high lights in the faces are rather too strong. This remark applies particularly to No. 611, "The Musicians" (they seem under-exposed), and No. 612, "Popping the Question" (the heads are out of focus); but the Messrs. Chaffin are working and striving in the right direction, and, with a little more well-directed perseverance, we believe, will attain to the highest excellence. We hope to see their works again next year.

8. For the best enlargement, landscape (in carbon), size not less than 20 inches by 16 inches, a first silver medal to W. M. Harrison, for his enlargement (untouched) No. 637. This is a view at Seaton, Devon, and is very fine in detail.

9. A first silver medal (special) is awarded to W. Brooks, Reigate, for his truly wonderful photographs of Caves, &c., taken sixty feet underground. The difficulties in a

ease of this kind must be immense, as they are taken by artificial light. Mr. Brooks had to deal with yellow rays, as well as with the darkness of the caves. By whatever process he did them, we consider the specimens sent triumphs of the photographic art; they have all the characteristics of photographs taken in open daylight, beautiful in detail, &c. The discovery is capable of being applied in various ways, and, in a mining country like Cornwall, it may be invaluable, as it shows that our deepest mines can now be photographed successfully. What next?

10. A special first bronze medal is awarded to Robert Faulkner and Co., for their powerful enlargement, "Dorothy Morrison," No. 585. This is wonderfully delicate in detail, fine colour, and altogether a very artistic production. Messrs. Faulkner and Co. exhibit several others equally good.

11. A first silver medal is awarded to David Hedges, for his Studies of Animals from Life, No. 596. These are in the artist's best style, and unapproached.

Reuben Mitchell, of Bolton, sends some fine examples of dry-plate work, No. 582 being especially good.

Adam Diston's carbon enlargement, "The Broken Toe," is a well-composed interior. No. 609, "Henry Kirk White in his Study," wants focus; the objects behind are too sharp; but Mr. Diston is working in the right direction, and we expect some fine specimens of photography from him. We hope to see his work here again.

Felix Bonfils sends several fine photographs from Egypt, &c., No. 634 being extremely good.

H. Garrett Coeking sends several splendid studies in his well-known style, No. 657, "Gitana," being remarkably good.

Messrs. Geo. F. Dew, J. Milman Brown, T. Nesbitt, and the Cleveland Photographic Company, send specimens of good and earnest work.

Messrs. W. H. Oakley and Co. send "Photographic Appliances," with many improvements in apparatus, &c.

AMATEURS.

The amateur department is also very well represented, and has several workers "running hard" many professionals. Charles A. Fernley, for instance, exhibits "Six Sketches near Reigate," which are photographic gems; but we cannot understand how Mr. Fernley, with his artistic feeling, could leave his skies so white; a little cloud here and there would make them perfect. A first bronze medal is awarded to his No. 707.

T. M. Brownrigg has a first bronze medal for his "On the Blackwater," No. 703.

Harry A. H. Daniel is awarded a first bronze medal for his "Cottage, Lynmouth," No. 717. He exhibits a good collection of photographs by the wet collodion process; some are exquisite in detail.

Other exhibitors sending good works are, Louis W. England, Henry N. White, Edward Brightman, J. Dudley Radcliff.

A first silver medal is awarded to H. N. White, Isle of Wight, for his splendid series of photo-ceramics. These would do credit to any professional photographer. Mr. White must have an intense love for the art, or he could not produce such work.

ON THE PREPARATION OF THE PAPERS EMPLOYED IN CARBON PHOTOGRAPHY.

BY ADOLPHE OTT.*

Formerly Chemist in the Establishment of Braun & Co., Dornach, Upper Elsass.

UNDER carbon photography is understood the photographic printing processes depending on the property of coloured gelatine, when mixed with a salt of chromic acid, and then dried, to become insoluble after being exposed to light. A sheet of suitable paper is coated with a thin film

of coloured gelatine (generally also mixed with other soluble substances); this is then sensitized in a solution of one of the chromates, and when thoroughly dried exposed under a negative. If the exposure be continued for a sufficiently long time, there is thus obtained a positive copy which only requires to be brought out or developed in order to obtain a picture corresponding completely with the negative, and possessing the great advantage that it does not fade like silver photographs, but is of unlimited durability, provided, of course, that, for tinting the paper, only permanent colouring materials—as Indian ink, indigo, madder lake, &c.—be used.

Now the developing process cannot be effected on the carbon paper itself, for however thin the gelatine film may be, it can only be rendered completely insoluble in those parts which are opposite to the perfectly transparent portions of the negative, and even there, with a comparatively short exposure, the insolubility cannot always be secured. Where, however, the negative image is quite opaque, or where there are half tones, the film will still be either entirely soluble in hot water, or will only become insoluble on its upper surface to a depth corresponding to the intensity of the half tones; the lower side of the film, which is in contact with the paper, remains completely soluble. If, therefore, it be attempted to develop the picture on the carbon paper itself, the whole film would directly detach itself from the paper, and float on the surface of the developing water; it would crumple up, and because of its exceeding tenuity, would, by tearing in pieces, baffle every attempt to stretch it on a support. Hence, before developing, it must be transferred to another paper; in this state the insoluble part of the film rests on the support, and the soluble part can with ease be washed away by hot water. As the whole operation started with a negative, the first positive on the carbon paper would be in the right condition, but on being transferred to the second paper it would again be inverted; in order, therefore, to set it right it must be transferred once more. We have therefore to investigate directions for the preparation of four kinds of paper—the carbon paper, the developing paper, the second transfer paper, and (in cases where an already inverted negative can be used where that as a second transfer is not necessary) the single transfer paper.

(1) *The carbon paper.*—For making this paper, various formulæ have been published* :—

	Nicholls.	Swan.
Gelatine ...	100	100
Sugar ...	50	50
Water ...	250	300 to 400.

When the paper is to be sensitized at the same time, three parts of a concentrated solution ammonium bichromate must be added to the above.

	Bollmann.	Fargier.	Vidal.†
Gelatine ...	100	100	100
Glycerine ...	33	—	13
Water ...	666	1000	666
Colouring matter —‡	...	12·5	4

These formulæ, as given in the books, are by no means satisfactory. For instance, the quality of the gelatine to be used is nowhere stated, and only in two cases the proportion of colouring matter and of the chromic salt given. Every one will also be struck with the difference—varying from 250 to 1,000—in the proportion of water, as well as in that of glycerine and sugar, varying from 0 to 50.

The question whether a carbon paper can be prepared with gelatine alone—without, that is, the addition of any sugar or glycerine—may be answered in the affirmative, provided that a soluble kind of gelatine is available, and that it is at once worked so soon as it is dry; otherwise the gelatine quickly becomes insoluble, and it is impossible to develop the image; an easily liquefied gelatine

* Compare A. Martin, *Handbuch der Email-photographie und der Phototypie oder des Lichtdruckes*, p. 233, et seq.

† In this case sensitized with 13·3 parts of the bichromate.

‡ *Traite Pratique de Photographie au Charbon* (Paris, 1877), page 113.

conduces also to the manifestation of other defects. A gelatine containing no sugar will, according to Husnik,* grow hard two days after sensitizing, and can no longer be developed; the addition of sugar offers many more points of attack to the hot water, and permits it to penetrate with greater ease into the layer of gelatine.

At Dornach, where for some years past carbon paper has been manufactured on a large scale, we find that 25 per cent. of sugar with (in some cases) 5 per cent. of glycerine, perfectly sufficed to render the film soluble to the required extent; but in a climate such as ours, the addition of glycerine is not always necessary, for in general the film of glycerine retains its suppleness without it, and we, therefore, as a rule, rested satisfied with the 25 per cent. of sugar. In dry climates the presence of glycerine may be advisable, and, in that case, 5 per cent. of that substance, besides the sugar, will be enough. The quantity of water should be from 300 to 400 parts, as in the formula of Swan. For sensitizing, 5 parts of potassium bichromate will suffice. In respect to the colouring material, however, regard must be had to the pigment used, and to the purpose which the paper has to serve; the limits will be from 20 to 50 grammes of colour to 1 kilogramme of gelatine. Relying on an experience of many years we can, with confidence, recommend the following formula:—

Gelatine	100 parts
Sugar-candy	25 "
Glycerine (when necessary)	5 "
Potassium bichromate	5 "
(Dissolve in 50 parts water)			
Water	300 to 400 "
Colouring material	2 to 5 "

One of the most suitable kinds of paper is that manufactured by Romain Talbot, which is sold in rolls 80 centimetres wide and 200 metres long; the weight of such a roll is 16·25 kilogrammes. At the manufactory of Braun and Co., the carbon paper is made in rolls 4 metres long, the weight of such a roll, when finished, being 630 grammes, and its price 62 Pf. (nearly 6d.). As will be seen from the price, this is not a paper of very first-rate quality, as, indeed, it is not necessary it should be, for the picture does not remain on it, but is transferred. It is further required that this paper should be, to a certain extent, porous, in order that it may be easily penetrated by the water in developing, and that it may quickly separate; these conditions are completely fulfilled by Talbot's paper. For the so-called transparent positive papers, which are employed in enlargement photography, a finer kind of paper from the factory at Malmédy is required.

As regards the kinds of gelatine to be used, those made by Nelson, Dale, and Co., 14, Dowgate Hill, London, and sold under the names of "Patent Opaque Gelatine," and "Patent Amber Gelatine," are certainly of excellent quality, but rather dear. We prefer the amber gelatine, on account of its lower price. Rouen gelatine is also a good sort, but that produced by Arnetre is of no use, because it causes the pigment to fade. Very soluble kinds like that made at Strassburg are also of no service, unless they be mixed with others. In the establishment of Braun and Co., at Dornach, Nelson's gelatines are exclusively used for transparent positive papers which are to be affixed directly to the glass; for other papers, where so great an adhesive quality is not required, a combination of one-third Strassburg and two-thirds Rouen gelatine is employed.

(To be continued.)

THE CHALLENGER PHOTOGRAPHS.

"It appears that we are still waiting," the *Daily News* remarks, "for the photographs brought home by the Challenger, which comprise, as our readers may imagine, one of the most valuable mementos of that expedition. Beyond the original cost of securing the valuable series of nega-

* Husnik *Die Heliographie* (Vienna, 1878), page 141.

tives, produced in every quarter of the globe visited by Sir Wyville Thompson and his friends, a large Government grant has been made to defray the expense of publishing the pictures, which will illustrate more forcibly than any written description the three years' voyage of the Challenger. We only trust that when the prints are before the public they will give more satisfaction than was given by those of the last Polar expedition. As the burden of securing these pictures was entirely borne by the public, one might have thought there would be little difficulty in securing a set by paying the cost price of production. Not so; never were photographs more jealously taken care of by the Admiralty, and the utmost this department consented to do was to print half a hundred copies and distribute them among the principal institutions and libraries of the Kingdom, to be buried among dusty archives and forgotten Blue Books. Nor were the Polar Expedition photographs of a nature to last very long. Although Government might very well have availed itself of several methods whereby prints of a permanent character could have been secured, the authorities preferred to have impressions in silver, with the fading of which every one is familiar. What the value of these sets of Polar photographs will be in twenty or thirty years may be readily conceived by all who have studied the changes in the family album. We do not know what is being done with the Challenger photographs, but the length of time that has passed may be a sign of better management. In any case, as the negatives have been produced by public money, there should be no difficulty thrown in the way of those desiring to purchase copies of such pictures as may interest them. Among the Challenger series are pictures that will delight students in almost every branch of science, while to the geologist and botanist they will be particularly useful.

PHOTOGRAPHING ON WOOD.

BY T. C. HARRIS.*

AMONG the many published formulae for photographing on wood, nearly all are defective at one vital point; that is, the block becomes wet during the operation. In this respect engraver's box-wood is peculiar, and to wet a block is generally to spoil it. In preparation, the logs are sawn transversely into wheels about one inch thick, and planed down to type height. As the trees are of comparatively small diameters, it is often necessary to glue several pieces together to obtain a block of a given size. To salt and sensitize a block in the usual way wets it, of course, and the final toning and fixing gets it thoroughly soaked. The surface on which the engraver works is endwise the grain of the wood, the pores of the wood running straight through. Water quickly penetrates these pores, thereby causing the block to swell and warp, and, when subsequently dried, very often does not regain its former level condition, which is essential. The small pieces composing the whole often expand unqually, thereby tearing them apart at the joints. Besides this, the glue in the joints becomes softened, making it liable to break in the press. The mere sensitizing of the surface will often cause the block to warp so much that it is impossible to get good contact in the printing frame. Rinsed negatives are required also, which is another trouble.

There are two ways of printing on wood which give good results, and do not damage the block in the least. From a negative of the subject desired, make a clear, thin positive on glass, by the wet collodion process. The positive should be of the proper size, on clean glass, without substratum. Tone and fix as a transparency, and lay in a dish of water containing a small percentage of sulphuric acid, to loosen the film. The film will soon become so loose that it can be easily stripped from the glass and transferred to the block. To do this safely, lay on the film a piece of wet albumenized paper a little larger than the glass. Press out the bubbles

* *Practical Photographer.*

and surplus water carefully, then turn back one corner of the paper, and it will come off, bringing the film with it. Have the block smoothly whitened with Chinese white in gum-water, and the surface slightly damp. It is now easy to transfer the film to the wood and remove the paper, when the block must be allowed to dry spontaneously.

Another way to print on wood is by a sort of photo-lithographic process. Coat paper with a thin, uniform coat of gelatine in warm water. Dry, and float a short time on a weak solution of bichromate of potash in water. Dry again, and expose under a negative till all the details are visible. Now roll the entire surface of the print with a printer's roller charged with lithographic transfer ink thinned with spirits of turpentine. Now soak the paper in a dish of tepid or warm water until the ink can be removed by rubbing gently with a soft sponge. All the ink, except the lines composing the picture, can be removed, when the print should be laid face down on the whitened block, and subjected to a heavy pressure in a common letter-press. The paper can be easily removed by wetting the back.

Another application of photography as a help to the engraver was discovered by the writer. Procure hard rubber, in smooth, black, polished sheets of about one-eighth of an inch in thickness. These are to be cut to the proper size, cleaned and albumenized the same as glass for negatives. The rubber plate is covered with collodion, sensitized in the bath, exposed in the camera, and developed in the usual way of making a negative. In fact, the whole operation is exactly the same as in making a ferrotype, on rubber instead of an iron plate, and a ferrotype bath and collodion are well adapted to the rubber. When a clean, sharp image is obtained, it is fixed in cyanide and varnished with a thin, transparent varnish, and dried by a gentle heat. The plate is now ready for the engraver, who will have a fine smooth surface and a clean drawing to work on.

When engraved, the plate is mounted on a wood block, and made type-high, and is ready for the printer. The rubber is somewhat more difficult to engrave on than box-wood, but the surface is much finer, and makes a more durable printing block. Unless more than one cut is desired, it is unnecessary to have it electrotyped, as wood-cuts are, but the original can be used in the press along with type, and as many as seventy-five or one hundred thousand impressions taken from it before it shows wear.

Correspondence.

FIRES IN STUDIOS.

DEAR SIR,—I beg to enclose an extract from the report of an inquest held on a fire on a photographer's premises in Adelaide, in which you will see that a witness makes the statement that cuttings from silvered paper are liable to spontaneous combustion, giving the Editor of the PHOTOGRAPHIC NEWS as his authority for saying so. As I never before heard, though a constant reader of your paper, of any danger in keeping silvered cuttings, I can't help thinking it a random statement without any foundation. The matter is of importance to photographers here, as regards their insurance policies, the companies thinking photography a very hazardous business, and as a consequence charging high premiums. It unfortunately happens that there have been two or three photographers' fires here recently, the origin of which could not be traced.—I am, sir, &c., AN ADELAIDE AMATEUR.

PS.—I have kept silvered cuttings for years, and have a stock now.

Captain J. H. Biggs deposed that as an amateur he had made photography his study for some years. The clippings of photographic prints referred to in the enquiry were composed of albumenized paper, sensitized with nitrate of silver, sometimes fumed with ammonia, toned with chloride of gold, and fixed by immersion in a solution of hyposulphate of soda. Such clippings were liable to spontaneous combustion, according to the Editor of the PHOTOGRAPHIC NEWS. Could not say how long after the pack-

ing together of the clippings combustion would arise. Knew of no other chemicals used by photographers liable to spontaneous combustion. The only one he could think of was gun-cotton. He had mentioned to some photographers the fact of the clippings being liable to spontaneous combustion.

By the Foreman—Considered the heat of the weather would accelerate the action of most chemicals. Did not understand the chemical action by which fire was produced—whether by damp or heat. Should think half a pound of the clippings would be sufficient to create the combustion.

[We have no reason to believe that the danger referred to exists. The question was referred to in the News some years ago, when it was alleged by a correspondent that unfixed clippings of silvered and fumed paper might be a source of danger. But certainly no such danger is to be feared from clippings of fixed prints. We have never known a case of spontaneous combustion of pyroxyline.—Ed.]

COMFORT IN LANDSCAPE PHOTOGRAPHY.

SIR,—I have been dabbling in landscape photography for about ten years, but never, till quite lately, succeeded in getting all my arrangement entirely satisfactory. It may interest your amateur readers (or indeed professional) to know my way of conducting operations. First, as to the process. Commercial dry plates, and an automatic changing box holding one dozen plates. No dark-room; for the development is conducted at night, over the kitchen sink, by the light of a non-actinic lantern. So far, perhaps, many others work in the same way. But now for my second point.

My second point is my very superior means of transport. Suppose I want to take some views about fifteen miles off. Well, there is no hurry over breakfast. I just take my folding camera (7½ by 4½), changing box full of plates, two or three lenses, and focussing cloth, and pack them in an old Stillman's developing box. This, weighing, when packed, under twenty-five pounds, is strapped on behind my carriage, the camera-legs in front, and the fifteen miles are covered, fairly easily, in two hours. No horse is required, for the carriage is one which has not been very long before the public, viz., the "Salvo-Quadricycle," made by some firm at Coventry. Anyone can ride them after five minutes' practice; and though the work is tiring at first, yet before I had had mine a month I did twelve miles in seventy-two minutes, on good roads. The prime cost is not too small, but one soon recoups one's self by total abstinence from medicine at 4s. a dozen, and by rapid improvement of general health. Altogether, though I do not generally point myself out as an example, yet in this matter I think I may.—Yours faithfully,

CONTEN.

Talk in the Studio.

ALLEGED ROBBERY.—In giving the details of an alleged robbery by a photographer, we are requested by Mr. Henry C. Turner of 299, Euston Road, to state that the charge has no reference to him notwithstanding the similarity of name. At Marylebone, Henry Turner, 24, photographer, of 11, Tyndall's-buildings, Gray's-inn-road, was charged with loitering at the rear of 33, Euston Road, at 1 o'clock on the morning of the 25th ult., supposed for the purpose of committing a felony. He was further charged with breaking and entering the workshop at the house on the 26th of April last, and stealing therefrom various articles value £5, the property of Frederick Cole, photographer. The evidence showed that the prisoner had formerly been in the prosecutor's employment, but left it in August last. He knew the premises well, and on the evening of the 26th of April the prosecutor locked up the premises safely, and on the following morning they were found to have been broken into and a number of things were missing from a table drawer which had been forced open and from the studio. An entrance had been obtained by the back door, which had been broken open. The police were communicated with, but nothing could be learnt of the thief or thieves. On the morning of the 25 ult., about one o'clock, a police-constable of the S Division found the prisoner crouched up on the top of the dust-hole on the back of the premises. He was asked what he was doing

there, but he made no reply and pretended to be drunk. He was taken into the Euston Road, and on being told that he was going to be taken to the police-station he became violent, and assistance had to be obtained before he could be got there. A key was found in his possession which was identified by the prosecutor as having been stolen on the night of the 26th of April. Detective Moody, of the S Division, searched the prisoner in his cell, when he then handed him some pawnbroker's duplicates. These related to articles that had been stolen on the 26th of April. Two other charges were also entered against the prisoner of breaking into and entering the shop on the 7th of May and again on the 18th of the same month and stealing a number of articles. The prisoner had nothing to say in his defence. Mr. Cook committed him for trial on all the charges.

To Correspondents.

J. A. B.—To work the method of finishing pictures in crayons introduced by Mr. Vanderweyde a few years ago, satisfactorily, personal instructions are desirable. Those who purchased the right to work the process were supposed to receive personal instructions as well. The proper crayons were also supplied to licensees. We cannot tell you with any certainty what crayons are used: we should think that ordinary soft crayons mixed with pumice stone powder would answer. The colour would depend on the tone of the picture: black, indian red, and brown umber would, we should think, serve. The pumice powder and crayon powder are mixed, and applied with a circular movement to the surface of the print with the ball of the finger. Probably Mr. Vanderweyde could give you more information if you communicate with him.

VENATOR.—We believe it is the custom, with the majority of high-class physicians, to give advice on moderate terms to those who cannot afford high fees, at certain times, very commonly to those applying personally before 10 a.m. One of the ablest oculists we know is Mr. Maekinlay, of 18, Stratford Place, Oxford Street. We are uncertain as to whether he gives advice in the way we have mentioned or not. That can only be ascertained by enquiry.

JOHN TERRAS.—The packet has not yet reached our hands. We will report on examining the prints. We know nothing of the lens you mention, save what we have seen in advertisements in the American journals; and we should take the claims there made with several grains of salt.

H. WILSON.—The printed slip, &c., were duly returned before we received your letter, and you doubtless have received it. We delayed in order to send on the other information for which we had applied.

H. BUTTERWORTH asks what is the difference in the finished result—that is, in the sensitive plate—between a bath plate and an emulsion plate. Theoretically they should be very much alike. The first is coated with collodion containing an iodide and a bromide. This is immersed in an aqueous solution of nitrate of silver, when, owing to the affinities which exist, a process of double decomposition takes place, which results in the formation in the collodion film of bromide and iodide of silver. In the emulsion plate the silver salts are formed in the emulsion itself, and, being insoluble but in a fine state of subdivision, they remain in suspension. There are some other practical differences. Bromide alone, for instance, is found best in emulsions, and the other products of the double decomposition—such as nitrate of ammoniac, &c., which in the bath plate remain, are washed from the emulsions. We have no doubt that emulsions will finally become universal for dry plate work, and it is probable that rapid dry plates will become very general for portraiture and studio work.

B. D. F.—You have used a strong toning bath, and used it too soon after mixing. There is no remedy for the bleached effect of which you complain when once the effect is produced.

UNFORTUNATE.—We cannot with any certainty tell you what is the best treatment for the solution, as we do not know the nature of the contamination. It is possible that making it alkaline with carbonate of soda, and long continued sunning may restore it; or, possibly, boiling will prove the simplest method. Failing this, throwing down with zinc will be best.

OLIVER PIPER.—We have not a doubt that the portraits in "Men of Mark" are copyright. It is not necessary to inscribe the word "copyright" on a picture, as all pictures are presumed to be copyright. We cannot tell you whether they are, or are not, registered; but being part of a book, they would come under the law of literary copyright.

CYMBRO.—We are always sorry to hear of such cases as that our correspondent mentions. But we regret that we have no means of aiding them. See an article we wrote on the subject some weeks ago.

RANGEL AND CO.—Received. Thanks.

J. H. B.—See a letter on the subject, and our note in the present number.

The Photographic News, June 13, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

LA POSTE AERIENNE IN FRANCE—PHOTO-ENGRAVING PROCESSES IN PRACTICE.

La Poste Aérienne in France.—Bearing in mind the important services rendered by carrier-pigeons in establishing a "poste aérienne" during the siege of Paris, the French Government decided some time ago to foster the training of pigeons by its own officials, in case, at some future period, these winged messengers may be called upon once more to carry photographic film despatches into beleaguered towns. The leaving of a besieged city in a balloon, and thus conveying news to friends outside, is a comparatively easy matter; but it is a task of some difficulty to convey messages through the enemy's lines into the city itself. How France was able to communicate with its capital when this was so closely surrounded by German troops is a story with which we are all familiar. By the assistance of the photographer and the carrier-pigeon, a postal system was established with marked success, and if only the pigeons had been better trained, hardly a letter would have miscarried from the provinces to the capital. To ensure a more trusty race of messengers is now the aim of the French Government, for, so far as photography is concerned, this part of the work is discharged in the most perfect manner. Something more than 100,000 messages were despatched from Tours and elsewhere into Paris, and although the "poste aérienne" was a make-shift arrangement, started in a moment, without adequate appliances, nearly half, or 50,000 messages, reached their destination behind the fortifications of Paris. To effect this, however, the photographers had to work with a will, for only three or four per cent. of the pigeons actually reached Paris. The despatches had to be repeated over and over again, and on an average the same message was forwarded by forty pigeons. Since, however, the films were so fine that one single pigeon could well have carried the whole 100,000 messages in a tube affixed to his tail, the question of weight never entered into the calculation at all, and each pigeon, when it started, carried as many letters as is usually carried by a mail train. In some cases, it may be remembered, the pigeons were very quick in delivering their messages, and M. Dagron, to whom is due in the main the development of the system so far as photography is concerned, quoted one instance of this which is well worth repeating. He quitted Paris in a balloon with his apparatus, and narrowly escaped capture, having to place his cameras and appliances in wine casks to pass them through the enemy's lines, for the balloon had fallen within the zone of investment. He lost much of his material, among the rest his pyroxyline; this was of a special make, prepared by Poullena and Wittmann, of Paris, and eminently suited for the microscopic films he desired to produce. He could not obtain the same article at Bordeaux, where he was stationed, and consequently sent in an order for some to the Paris firm. His message left on the 18th January by carrier pigeon, and on the 24th of the same month (six days afterwards) the goods were lying at his disposal at Bordeaux, having been forwarded, according to instructions, by the first balloon. The pigeon in this instance required only a dozen hours to traverse the distance from Poitiers to Paris. But this was an exception to the rule. Most of the birds were not of proper breed, or, in other words, "homing" pigeons, for the so-called carrier is an impostor, and could not travel fifty miles to save his life. Any pigeons that could be obtained in Paris were sent out in the balloons in the hope that they would fly back again with the messages, and many were quite untrained. A pigeon, according to Mr. Tegetmeir,

a great authority, only flies by night, and as the balloons left Paris at night in the dark to prevent discovery by the Germans, the birds, if untrained, had little chance of finding their way back. The French Government now keep a quantity of "homing" pigeons in their chief fortified towns, twelve of the most important being chosen, not forgetting Paris. Officers and soldiers are selected by Government to train the pigeons, of which at this moment there are said to be no less than 6,000 in the French army. Means are also being taken to encourage the training of pigeons of burghers and citizens, and State prizes are to be instituted. It would be well if the photographer and photographic interest were as thoroughly cared for by the French Government, but we believe that the French Post Office disposed of all its balloons and photographic apparatus, which had stood the establishment in such good stead, as soon as the war came to a termination.

Photo-Engraving Processes in Practice.—Publishers and art-draftsmen are beginning to look with contempt upon "processes," by which they mean photographic methods of converting a sketch or drawing into a printing block; and, judging from results that meet the eye every day, they have much reason for their dislike. But there are processes and processes, and although the best of them cannot compete with wood-engraving, good impressions are to be secured, if the details of the method are carried out with skill and deliberation. The clogging of lines with ink, and the presence of minute specks or spots that give the picture an unclean aspect, are frequently the result of carelessness or hurry as much as anything else, and might be avoided if time were taken to free the metal or stone from such imperfections, supposing there were no means of preventing their formation. At the same time, photography cannot at present do what many people imagine. It is perfectly possible to secure either a phototype or surface-block from a printed engraving of almost any description; but it is not within the power of any "process" yet brought forward to convert the ordinary draughtsman's sketch into a block to be printed with type in a printer's press. And the reason of this, as we have before pointed out in these columns, is not far to seek. When a woodcut appears printed upon paper, it is in pure black and white; some of the lines may be very fine and very close together, but in all cases they are black, and there never is—or rather, never ought to be—anything grey about them. Such an impression as this would give little difficulty in reproducing by photography. But let anyone examine the drawing of a draughtsman's upon box-wood before it goes into the hands of a cutter, and he will at once see how difficult it would be to try to secure a photo-type from it, an intaglio that could be used in the printing press. By Woodbury-type the problem is to be solved; but then we must remember a transparent ink is used, and not one that is black whenever it touches paper. Again, by surface-printing, as in collotype, a block might be secured; but this is not to be worked in a printing press. The draughtsman's sketch, even if he has used a jet-black pencil, is not made up of jet-black lines. When he works with the fine point of his pencil, it is the case; but he has a habit of turning his tool upon the side and producing a broad grey line, which, if reproduced by the photographer as a broad black one—and he would have no other alternative by the processes in everyday-use—would at once spoil the composition. The wood-engraver, when he sees these broad grey lines, splits them, so that in printing one or two white intervals run the length of them, and lightening the mark considerably. But the photographer cannot interpret the draughtsman's work as the wood-cutter does, and hence he fails; perhaps, when we can better produce a grain by photographic or mechanical means, the camera will be able to do more in this branch of industry towards assisting the engraver.

ON THE FUTURE USEFULNESS OF PHOTOGRAPHIC SOCIETIES.

BY ARTHUR BRITTLEBANK.*

THE future usefulness of this Society cannot be otherwise than interesting to all members who are earnest in their endeavours to promote its well-being, who look upon photography as a scientific art, and not merely from a pounds, shillings, and pence point of view, though I fear there are many who attend the meetings merely as a pastime—to pick up "wrinkles," as they call it, and see if there is anything fresh that can be appropriated by themselves as a means of profit, without contributing in any measure to the general good themselves. This, I take it, is not the spirit that should animate our thoughts.

I, with many others, would like to see a broader and a nobler purpose, as it were, pervade our professional transactions, that should stimulate us to exertion, and, whilst affording individual pleasure, would also open up fresh trains of thought in others, and be of lasting benefit, not only to ourselves, but to our profession.

I have for some time thought that this Society is not known as it should be, that its workings and doings have not been sufficiently expanded or directed into the proper channel, and that it does not confer upon its members the full benefits which an organised society, constituted as this is, should have the power of bestowing.

As an illustration of this, note the entire absence of young men amongst us—I mean young men from sixteen to twenty-two years of age, this being the time of life when a man is most capable of receiving instruction and ardently enjoying the pursuit of knowledge, however difficult it may apparently appear. Then he is full of hope, and ambitious to excel in the profession or calling which he has chosen, and it might be naturally thought that class-institutions ought to be crowded with young aspirants to fame and zealous students in the field of knowledge.

I am, then, of opinion that we do not offer or hold out inducements sufficiently attractive and valuable in themselves to tempt our young professional brethren into this very often up-hill work, often involving great self-denial, mature study, and constant application. The papers that are read here are undoubtedly often of great interest and value to the profession generally, and bring to light much valuable information and induce research in many minds that would otherwise remain dormant. This is all very well for matured workers, but, at the same time, I think we ought to do something for the younger members of our profession, and this can be done in many ways.

There does not exist in this vast metropolis, the capital of the world, any recognised school in which a young man can obtain regular training in the higher or more advanced branches of this profession. There are hundreds of young men going through the daily routine of their work, who know next to nothing of the "why and wherefore" of what they are doing; and in many instances employers are unable, from want of knowledge themselves, to supply even elementary information.

This is a state of things for which it is very desirable we should find a remedy, and an incalculable boon would be conferred on the profession by the establishment, under the governance and direction of a properly-constituted committee, of regularly organised classes, which young men could attend and cultivate their tastes and talents in a satisfactory and profitable direction. I am sure we have men of intellect amongst us capable of directing the studies of young men, and I feel equally certain that they would be generous enough to give a portion of their time for the furtherance of such an important object; and when the nucleus of such a staff of voluntary teachers was once formed, others, of less aspiring natures in the first instance, would gladly enrol themselves for service in the good work.

Hearing papers read is, I fear, of little use to young men without the elementary groundwork is thoroughly secure.

* Read before the South London Photographic Society.

There is too much of the mythical "royal road" to knowledge about them, and the knowledge is obtained too easily—that is, without study—and in many cases would be as easily forgotten. I am, therefore, decidedly of opinion that the only solid knowledge that will benefit a man is that obtained by close application and observation, together with continuous and properly-directed study.

I am now going to submit for your consideration the question as to the propriety of founding three classes of instruction—a chemical class, an optical class, and a general photographic art class, and I think that under these headings all professional culture can be easily classified. My desire is to see photography raised above that level where the mere manipulation of a lot of bottled solutions constitutes "the art."

Chemistry, optics, and general science are so intimately allied to photography that I think we shall be doing good work on a solid foundation in striving to promote a knowledge of these subjects. This is the kind of thing that will attract young men to our Society. Let there also be periodical examinations to test the proficiency that each member may have attained in all or any particular branch, let them be given certificates according to their merit, and their names be gazetted in our professional journals. Depend upon it there is nothing like competition to stimulate the mind and bring out the abilities, and I hope to see the time when young men will look with honest pride and pleasure on the prizes and certificates which their merits have gained them in these examinations. When this wished-for time shall arrive, the first question asked by an employer, when he is about to engage an assistant, will be—"Have you passed? and what is your grade?" This will assuredly bring intelligent men to the front, and they must claim precedence in all future business transactions, whatever the branch may be; it will also gradually raise the *morale* of the profession. Photographers will then be looked upon as men not only skilled in the craft they pursue, but as men of learning connected with the most fascinating sciences that can engage the attention of intellectual minds. Who can look back on such names as Brewster, Faraday, the Herschels, Tyndal, and a whole host of other honored names of men who have done so much unselfish good for the benefit of mankind, and reduced chemistry to an exact science, capable of being demonstrated with mathematical precision and rule?

Who will affirm that a photographer should not have a intimate knowledge of all articles that come under his daily notice? And, further, would he not be a better man if he also possessed a knowledge of the atomic theory of the combinations of the different elements of nature, and of the combining proportions of these different elements to form new compounds? How is it that certain men have produced such wondrous changes in photographic manipulation? Simply because they have been able to bring to bear a whole storehouse of chemical knowledge to the subject in hand. We have all in our experience had more or less proof of the value of little things, and how giant results have been obtained in the field of science by men hemmed in, as it were, on all sides by hindering circumstances, strong only in their indomitable perseverance of manly courage; men who have conquered and won in spite of many trials, privations, and failures; men who have thought they could never do enough for others, yet have esteemed gratefully any little kindness done to themselves, and have produced from the very *refuse* of chemical works grand, glorious, and world-known results, as in the case of aniline dyes.

Then, with regard to optics: ought not a photographer, by virtue of his professional associations, to be thoroughly acquainted with every form and description of lens? Certainly; and also to be able to tell, straight off, the best form for any particular purpose, and not, as is now the case in too many instances, have to rely on the opinion or recommendation of the dealer. I am of opinion that there is as much much, and often more, paid for a name than there is for the article purchased; and this arises solely from the

ignorance of even the elementary laws of optics in the purchaser.

The course of study I am advocating would soon tend to alter this condition of things, and a man would not then go to a maker, or possibly only a *seller*, blindly ignorant of what he was going to buy, and almost of what he required. He would know beforehand exactly what would suit him without asking any questions, and there would not be so much silly and vexatious discussion as to whether this or that maker's lens were quicker or slower than those of someone else. He would know that rapidity depended upon aperture and focal length, and be able to tell the why and the wherefore of everything with which he has to do in his professional capacity.

The study of optics is one of the most interesting and fascinating for the young photographer, ever yielding fresh beauties, and leading him by easy gradation to master all studies of a kindred nature.

See what it has done for such shining lights as Kepler, the Herschels, Newton, and other illustrious astronomers, and what they have been enabled to achieve over the old system followed a thousand years ago. See how a profound knowledge of optics has enabled these men of giant intellect to tread, as it were, upon the boundless empire of space, and to map out in their order the countless stars, to chronicle their courses, regular or erratic, to know their times and seasons, and to be intimate with heavenly constellations not dreamt of before. These noble-minded pioneers have been the means of advancing some of the most sublime speculations that have ever engaged human thought—thoughts that will last the world's existence, and give impetus and direction to all future philosophers. Here, then, is a charming as well as a useful study; and I claim that what a knowledge of optics has done for astronomy it can also do for photography as an art but yet in its infancy, thus giving a boundless field for enterprise and research.

Now we come to "art" or artistic knowledge, and I see no reason why some of our photographic studies should not in themselves possess as much interest as the magnificent productions of the grand old masters, whose works are always cited as the perfection of artistic labour. Art can be put into a photograph on paper as well as into a painting on canvas; but a man must be an artist to do it, and have given art as a study a good share of attention, so that in some modern measure he may possess that animating spirit that stops at nothing short of perfection. His eye must be trained to graceful, beautiful lines; he must study the effect of light and shade, composition, and harmony. But none of this can be attained by merely reading or hearing papers read. The subject must be worked at, and young men should attend one of the many excellent schools of art established under Government inspection in the metropolis and most of the principal towns throughout the country, where they may receive the ground work of an art-education that cannot but be of immense benefit to them in after life, whether applied to the profession they are following, or in enabling them to examine with a critical eye any works of art that may come under their notice.

This, then, is but a brief outline of the future usefulness to which the energies of this Society might be legitimately and profitably extended, and I only regret that I am unable to do full justice to the subject. But I hope the question will be put to this meeting and see if something cannot be agreed upon and commenced at once in this direction; and if any of the propositions should be entertained, no one will be more pleased to lend a helping hand than myself.

ON THE FADING OF SILVER PHOTOGRAPHS.

BY F. A. WENDEROTH.*

THAT photographs will fade more or less, sooner or later, photographers as well as the public are by this time aware,

* Philadelphia Photographer.

but the thought to give up silver printing, with its facilities and unsurpassed beautiful results, is not much cherished either by professionals or by amateur; even if there was a new and better process offered, it would be accepted with reluctance, as we all know what time and labour it costs to master a new process. But has there anything new been offered that for general application is better than silver? One who reads the following remarks by the Editor of the English PHOTOGRAPHIC NEWS would be inclined to think that there was. He says: "When permanent printing processes exist, it is amazing that another silver print is produced." Reading this, I wondered what he meant; certainly not the carbon processes, which (allowed that when carbon alone is used in the form of ivory or lampblack for colouring matter, one of the substances needed for their production is permanent), for general use is impracticable, as most of those who have tried it can testify to. A large part of the business of portrait galleries is touched-up work, either painted, india-ink, or crayons. To use carbon prints for this kind of work is out of the question, as its surface, being either collodion or non-absorbing gelatin, is even a great deal worse than albumen, and water colours applied to it when mixed with gum will crack off as soon as dry; or, without gum, will rub off by slight touch. It is even worse than to paint on glass with water colours; and how to finish with crayons is an enigma to me.

Mr. Willis, Jr.'s, platinotype process is too little known yet to determine about its adaptability to studio work. It is a pretty general opinion with photographers that a process where the image is produced by development is not very desirable; and another drawback will perhaps be found by having to float each print separately on two different solutions, but practice will soon settle this point.

The last processes to be considered are the mechanical printing processes, by some of which very excellent results are obtained; but the expense, labour, and time required in their practice make them unavailable for single prints or small quantities, as no plate can be made with the shadow of paying a small profit from which five dollars cannot be realized as a minimum; so, at least, I have been informed by different parties who work these processes commercially. Where large numbers of copies are required, these processes will certainly supersede silver printing, but this business will go into the hands of large establishments.

In investigating the fading of silver photographs, the first and most important question to be answered is: Are the silver and gold compounds which form the visible image permanent? Which, I think, can be answered in the affirmative, as everybody owns, or has seen photographs taken at various times which are perfectly preserved. I myself have some twenty years old, which are perfectly preserved, but all the rest have faded and discoloured to a greater or lesser extent; but the most convincing proof I found of the perfectly unchangeable nature of the image is in all those of my coloured pictures called ivorytypes, made from ten to twenty years ago. The photographs constituting these pictures were taken on plain paper, some developed by the gallic acid process, some the ordinary ammonia-nitrate chloride silver; some small, some as large as twenty-five by thirty inches, and cemented with hot beeswax on to plate-glass. By this means the paper was perfectly saturated with the wax, enveloping the image completely, and shielding it effectively from atmospheric influences. In none of those ivorytypes that have within the last few years come under my notice can there be the least trace of fading discovered; the most delicate tints are perfectly preserved. There is not the smallest spot or stain visible, and the painting and photograph are in the same harmony as on the day when done; so unlike most painted photographs, where the silver image has disappeared, leaving the paint in unsightly daubs.

I am sorry to say that most of these ivorytypes are more or less discoloured in their transparent parts, I suppose by the oxidation of the wax where it was exposed to atmospheric influences; but where it was protected from these, as in those

parts of the work where body colours had been employed (which are mostly metallic oxides), enclosing the wax between the glass and the paint, the tone is unaltered. These ivorytypes were made during a period of twelve years, and I cannot guarantee that the photographic part of them was done on all in the same manner; but they are all alike perfectly preserved, whereas plain photographs, on plain paper, made at the same time, and under the same circumstances, and kept framed in a dry room, have more or less faded; showing distinctly the preservative property of the wax.

The next question to be considered is: What makes silver prints fade? Three main causes have been assigned as conducive to the fading of silver photographs: the mounting materials, the presence of soda, and outside influences.

To test the first, some prints made in the ordinary way, and well washed, were mounted with some decomposed starch or gum; others, with fresh, were exposed in a very damp and impure atmosphere for over one year, when they showed slight fading all over, uniform, no difference with sour or fresh mounting material, settling this point. To test the second point, the presence of soda, prints from which the soda, after fixing, had been removed with blotting-paper only, were, in connection with well-washed prints, exposed under several thicknesses of very moist blotting-paper for three days and nights, after which time both showed signs of fading; those with free soda being a little lighter, and the tint of the image somewhat more brown than the washed ones. This result surprised me, as I expected to see the soda prints perfectly destroyed; and I am convinced that a trace of soda left in prints which are kept under favourable circumstances will not affect them to any noticeable extent, and that the presence of soda in prints is not of so great account as generally supposed.

To test the effect of outside influences, prints made in the usual way, and mounted with fresh starch, were one half of the surface covered over with sour starch, and exposed with those mentioned above as having been mounted with sour starch to the same influences. After one year's exposure the one-half covered over with the sour starch showed very distinct fading in proportion to the varying thickness of the starch covering; whereas the uncovered halves were but slightly affected. Other well washed prints, mounted with fresh starch, were exposed under several thicknesses of blotting-paper which had been well moistened with hyposulphite of soda fixing solution, and after an exposure of several hours were almost destroyed. These results convinced me that outside influences are the most effective in regard to the fading of silver photographs, as likewise illustrated by the preservation of the above-mentioned ivorytypes.

Silver photographs made on different papers are influenced differently, and withstand the destroying elements differently. Albumen prints, with very few exceptions, fade and discolour simultaneously; prints on plain paper fade, but do not discolour, at least the paper does not more so than ordinary paper under the same influences. Since the introduction of highly albumenized papers this discolouration has very much increased. This difference is very marked on prints kept in an album for fifteen years, the whiteness of the paper of which has suffered but little, whereas prints made within the last few years have very much discoloured, the first ones being on single, the last ones on double albumenized paper.

Another decided difference is in the tint of fading prints on these two kinds of paper. On the single and on plain paper the remaining tint of the image is blackish, whereas on the double paper the remaining tint of the image is mostly brown or reddish-brown, always on a more or less discoloured albumen film. In fading out silver prints artificially there is a marked difference in the way different substances attack and change the colour of the image. Cyanide of potassa and hyposulphite of soda seem to attack the tint which is supposed to be produced by the gold, first

changing it from purplish-black to muddy brown, whereas sulphuret of potassa attacks the reddish tints first, changing the tone of the remaining image to a pure black.

Cyanide of potassa does not change the tint of the albumen, but sulphuret of potassa turns it from yellow to brown, according to length of exposure and thickness of albumen film.

It will be asked what produces the difference in the amount of fading of silver prints made on the same paper under similar conditions. This, I think, in most cases, can be explained by the difference in strength of the negatives, difference of albumen film, over or under-printing, and consequently great difference in the changes produced by the gold toning bath.

I think it admits of no doubt that prints made from strong negatives, consequently stronger printing and gold toning, will resist fading influences better than those made from thin negatives and slight toning.

Prints on thinly albumenized paper permit of a deeper incorporation of the image in the body of the paper support, and having less organic matter to expose to atmospheric influences, will suffer less and keep an even surface even after the application of water. This is entirely different with double albumenized papers. Prints on these papers, when closely examined after being mounted, will be found to have cracked into millions of particles, but firmly adhered to the paper; after the application of water, these little pieces curl up, leaving open seams between them, giving free entrance to their great enemy, the sulphuretted hydrogen of the atmosphere, and the body of the albumen film being of considerable thickness, the absorption of moisture will be greater; consequently, the process of fading is more energetic and quicker than with single albumenized paper. I think the sooner these highly albumenized papers are discontinued the better.

As it is my conviction that silver prints suffer most from outside influences, and that, for want of anything better, we will have to use the silver processes for who knows how much longer, I have directed my labours of late to produce prints that will resist these influences, with what success you can judge for yourself by the accompanying samples. Prints made in this way were immersed simultaneously with ordinary prints in solutions of cyanide of potassa, hyposulphite of soda, and sulphuret of potassa, and came out uninjured, whereas the ordinary prints were completely destroyed, and a prolonged exposure over a hot solution of sulphuret of potassa failed to attack them in the slightest degree, and I think that silver prints which can withstand these tests might be considered as permanent as most other things that are considered so, or as much so as reasonably could be expected.

PHOTOGRAPHY AND FORTUNE-TELLING.*

SOLOMON, had he lived now, would scarcely have been able to say that there is nothing new under the sun. The combination of the art of photography with the cheat of fortune-telling is, at least, unique. An inventive genius named Thomas Jennings, or, as he preferred to call himself—from motives of modesty, perhaps—Thomas Henry, must be credited with the discovery of this new road to affluence. Mr. Jennings, who up to the end of last week carried on business at Cooper's Road, Old Kent Road, displayed in his operations that sublime simplicity which is one of the special characteristics of the highest order of ability. He merely asked people to be duped, and hundreds, if not thousands, at once kindly complied with his polite request. In April last the ingenious photographer seems to have inserted in various papers an advertisement headed "Important," to the effect that unmarried persons, sending their description,

* South London Press.

date of birth, and eighteen stamps—this latter item, of course, on no account to be omitted—would receive in return "beautiful artistic likenesses of their future husbands or wives," together with "my wonderful fascinator and love secret, carefully sealed."

The number of persons duped by this very transparent device may be guessed from the fact that the Commissioners of Police in a few weeks received hundreds of letters complaining of the fraud practised on the writers; while six hundred portraits of ladies and gentlemen were found on the premises occupied by the clever Mr. Jennings, to say nothing of thousands of printed circulars and letters from Australia, China, and other places abroad. Some correspondents suggested that the fortune-telling photographer should predict for them the winners of the Derby and the Oaks, and a damsel of the mature age of fourteen was extremely anxious to behold the portrait of her future lord. Mr. Joseph Dell, who is somewhat vaguely described as "a salesman," answered the advertisement, and complied with its conditions, whereupon he received the photograph of a young lady, and a printed paper informing him that he would be married to her in nineteen weeks. As, however, Mr. Dell is only four-and-twenty, and has already entered the bonds of matrimony, he considered the contingency improbable, and forwarded the circulars as well as the photograph to the police. One of these documents spoke of "a magnetic secret, so fascinating in its effects as to make true love run smooth," which was to be obtained for the ridiculously small sum of two shillings. For a like amount "the Spanish love secret, discovered by a native of Madrid," was procurable. And for twenty-four stamps also "How to fascinate" was sold by the bottle. The flavour of this last compound is described as delicious, "it captivates the senses," and, thanks to its aid, no young lady or gentleman, according to Mr. Jennings, need pine in single blessedness.

"A handsome banking account," has rewarded the exertions of this amiable and enterprising photographer; but genius is not always appreciated, police magistrates are very often the most prosaic of mortals, and they absolutely decline to encourage the chivalrous generosity which, for the absurd consideration of two shillings, offers to make the course of true love run perfectly smooth. Mr. Slade, indeed, has committed the crafty Jennings to hard labour for three months, stigmatizing him at the same time as a rogue and vagabond. This is disheartening; but the thought of his handsome balance at the bank will no doubt serve to console the modern wizard and dealer in photographs and love-philters during his enforced seclusion from society. By the time he emerges from his quiet retreat at Wandsworth, Mr. Jennings will no doubt have devised some new means of adding to his resources. He will find plenty of fresh gulls—people with money, but without brains—and we are inclined to agree with Mr. Montagu Williams that his dupes deserve very little commiseration. It may be said of most of them, we suspect, that they never half believe in the imposture to which they yield, and that—

Doubtless the pleasure is as great
Of being cheated as to cheat.

WE mentioned the first hearing of the case above referred to a fortnight ago. Last week it was again brought forward on remand at Southwark, when Thomas Henry, *alias* Jennings, described as a photographer, living at 42, Cooper's Road, Old Kent Road, was charged with obtaining sums of money from a large number of persons on pretence of 'telling their fortunes.' Mr. Montagu Williams defended the prisoner.

It appeared from the statement of Inspector Fox that an advertisement, of which the following is a copy, appeared in a weekly publication in April last:—"Important.—Any

unmarried persons sending their description, including date of birth and eighteen stamps, will receive in return a beautiful artistic likeness of their future husband or wife, also my wonderful fascinator and love secret carefully sealed.—Address, T. Henry, 42, Cooper's Road, Old Kent Road." In consequence of that, the Commissioners of Police had received hundreds of letters complaining of the fraud practised on the writers, and the result was the apprehension of the prisoner on a warrant.

In addition to the evidence given last week, Joseph Dells, a salesman, residing in Tanner Street, Barking, said that on the 6th of April he saw the advertisement in question, and in consequence of that he forwarded a letter to Mr. Henry, of which the following was a copy:—"Lodge Farm Villas, Lodge Road, Rippleside, Barking, Essex.—Sir, seeing your advertisement I shall be obliged if you will send me a photograph of my future wife, for which I enclose eighteen stamps. My friend has recommended me to write to you, as he firmly believes in you, and is satisfied with what you have done for him. I am rather dark, dark hair, loving disposition, fond of home and children. My age last birthday was nineteen years. Hoping to hear from you soon,—Yours truly, J. THOMAS.—To Mr. Henry, 42, Cooper's Road, S.E. PS.—The date of my birth, August 23, 1859." In answer to that letter, he received a photograph of a young lady and a printed paper, informing him that he would be married to her in 19 weeks, and asking him to recommend the writer to his friends. Witness added that he was 24 years of age, and was married. In answer to Mr. Slade, he said one of the printed circulars sent to him was relating to a magnetic secret, which was "so fascinating in its effects as to make true love run smooth," which could be had for 24 stamps; also the Spanish love secret, discovered by Signor Andaluza, a native of Madrid, to be had for 24 stamps from Mr. Henry. There was another circular enclosed, "How to fascinate," at 2s. a bottle. The flavour of the latter was described as "delicious, and captivates the senses. No young lady or gentleman need pine in single blessedness."

Inspector Fox produced upwards of 600 portraits of ladies and gentlemen found at the prisoner's place. He also found thousands of those printed circulars and letters from Australia, China, and other places abroad. Some of the letters asked for the winner of the Derby and Oaks. One letter came from a girl 14 years old, asking for the photograph of her future husband. Witness had ascertained that the prisoner kept a handsome banking account in the name of Jennings, and that on his marriage certificate he went by the name of Nodes. No doubt, from the letters and documents he found, the prisoner had been for some time carrying on a very successful fraud on the public. Among the letters were several declining to accept his advertisements at any price. Witness added that there were a number of other witnesses ready to give evidence.

Mr. Williams said that after the decision of "Marsh v. Hilton" he was satisfied that the magistrate could not do otherwise than convict the prisoner under the Vagrant Act; but, as the persons who had consulted him were not entitled to much commiseration, he thought the ends of justice would be met by the prisoner finding bail to come up for judgment when called upon. It was the first case of the kind in this district, and it would, no doubt, be the last. Had the magistrate power to inflict a penalty he would be urged to do so.

Mr. Slade said that the statute gave him no power to inflict a penalty in such a case, even if so inclined. The prisoner had pleaded guilty to shameful practices which must be put a stop to by the strong arm of the law. He was, however, unable to inflict the punishment he deserved, but he should put the law in full force by sentencing him to three months' hard labour.

CAN PERMANENT PHOTOGRAPHS BE PRODUCED?

WE reprint on another page an article by a Philadelphia professional photographer, of some position, on the fading of silver prints, who affects to doubt the existence of any available and practical process of securing permanency, and enters into a defence or apology for silver printing. It is somewhat late in the day to argue the question of carbon *versus* silver! Nevertheless, silver has so many claims to affectionate consideration, that one readily sympathizes with its champions. It was the first process whereby photographs were produced, and it has been brought to such a state of perfection as regards results, that we readily concede anything which can be urged in its favour, however hopeless it may be to change the note of photographic progress. We should not have felt called upon, therefore, to notice Mr. Wenderoth's remarks, beyond reading them with interest, but for the fact that he in some degree challenges our published opinion on the subject, quoting a remark from one of our articles to the following effect: "When permanent printing processes exist, it is amazing that another silver print is produced." After quoting this remark, Mr. Wenderoth adds: "Reading this I wondered what he [the Editor of the PHOTOGRAPHIC NEWS] meant; certainly not the carbon processes," and so on. That Mr. Wenderoth, and any puzzled by a similar "wonder," may be assured of what we did mean, we must reaffirm the remark, and add, the carbon processes, certainly—or, as they should be more correctly termed, the pigment processes. If permanent pigments be employed, in which there is no difficulty, then the prints produced by these processes are permanent beyond a question. And as permanent processes exist, we may, very legitimately, repeat that it is amazing that another print by a fading process exists. The carbon processes are, according to Mr. Wenderoth, for general use impracticable, because "a large part of the business of portrait galleries is touched-up work, either painted, india ink, or crayons," and "to use carbon prints for this kind of work is out of the question, as its surface, being either collodion or non-absorbing gelatine, is even a great deal worse than albumen; and water-colours, applied when mixed with gum, will crack off dry; or, without gum, will rub off by slight touch." On reading this, we are, indeed, tempted, as was Mr. Wenderoth, to "wonder what he means!" We thought that the time when the large proportion of the work of the professional photographic portraitist was all "touched up work" was long since past, and that photography pure and simple now constituted the staple of the majority of good studios. However, of the nature of the business in American studios we know probably

much less than Mr. Wenderoth. But of the fitness of pigment prints for colouring, it is manifest that Mr. Wenderoth knows much less than it is desirable that he should know, and much less than is the fact. When pigment prints are to be finished in water-colours, it is not necessary or customary that their surface should be treated with collodion. But failing this, he says, it must be "non-absorbing gelatine." Where did Mr. Wenderoth meet with such a material? The material of a pigment print is in reality no longer gelatine simply: it is gelatine changed by combination with a mineral substance and the action of light, as leather is chiefly gelatine changed by a "tanning" material. But the gelatine, although essentially changed in both cases, and made much more durable, does not in either case become non-absorbent. A pigment print is in no wise unfitted for finishing in water-colour. We have, indeed, seen some of the most charming water colours ever produced by the aid of photography produced on a carbon basis by a portraitist who, whilst still sending out silver plain prints, scruples to send out skilled artistic work on a basis less permanent than carbon. As one of the earliest experimentalists with Swan's process, and the producer of the first book on the subject, we made early experiment in painting both in oil and water-colour on a carbon basis, and satisfied ourselves of the fitness of the surface for either. For crayon work, it seems to us that there could be less difficulty than is presented by albumenized paper. Any surface requires treatment to render it fit for the easy applications of crayons, and carbon prints certainly not more than others.

Our reference was, as we have said, to pigment printing, and the marvel that fugitive prints should continue to be produced after a method of producing permanent prints was known. But Mr. Wenderoth deals with other methods in a somewhat too summary manner. Mr. Willis' platino-type process he thinks is too little known to determine about, and regards it as a drawback that each print has to be floated separately on two different solutions! Well, it is not likely ever to be much known if such initial objections are allowed to have any weight. To how many solutions, we wonder, are silver prints treated! The paper is floated twice, once on the salting or albumenizing solution, and once on the silver solution, besides the operations of toning, fixing, and washing.

We need not follow Mr. Wenderoth into his enquiry concerning the fading of silver prints. That the fading is only too common, is clearly admitted. The most common cause, according to Mr. Wenderoth's investigations, is outside influence, that is, atmospheric or other similar agency. He finds prints protected by wax remain good. That wax, collodion, and other similar preservative agencies give increased tenure of existence to silver prints we have often enforced. The use of strong negatives, deep printing, and deep toning, he also looks upon as aiding permanency, and of this we think there can be no doubt. Highly albumenized paper he also regards as a cause of fading, in which he may be right. But the true source of permanency is, we repeat, emphatically in the disuse of silver and the use of permanent pigments.

EXTRA MEETINGS OF THE SOUTH LONDON SOCIETY.

THE zeal of our South London friends is not satisfied with having already more than the regulation number of meetings in a year. They meet from October to June monthly. In winter they have also a technical meeting. They have an out-door meeting in the summer, and a social reunion at the house of their hospitable and genial President. They now propose to meet during the recess, and one of their zealous members offers the use of his studio for the purpose. We give this prominent position

to such worthy enthusiasm, and commend such a society to any metropolitan photographer very much in earnest in his profession.

Here is Mr. Brittlebank's letter:—

"DEAR SIR,—I shall be glad if you will announce to the members of the South London Photographic Society that I intend placing my rooms at their disposal for the purpose of discussion every Wednesday evening, from eight till nine o'clock during the recess of the above Society. The first meeting will take place on Wednesday, June 18th.—Yours truly,
"A. BRITTLEBANK."

"P.S.—Members intending to be present will oblige by notifying the same the day previous.

FRENCH CORRESPONDENCE.

M. DE LAFOLLYE AND M. CHARDON'S EMULSION—OTHER COLLODIO-BROMIDE PROCESSES—M. FERRIER'S METHOD OF USING GELATINO-BROMIDE PELLICLE—PHOTOGRAPHY WITH PLATINUM SALTS—GERMAN PRINTS IN FATTY INKS—NEW TRAVELLING APPARATUS—OBJECT GLASSES BY M. STEINHEIL—NEW PHOTOGRAPHIC BOOKS—SUBSCRIPTION IN AID OF THE NIEPCE MEMORIAL.

Experiments of M. de Lafollying with Emulsions.—At the monthly meeting of the Photographic Society of France held on the 6th June last several very interesting communications were brought forward. As was stated in the PHOTOGRAPHIC NEWS for the 9th of May, page 224, M. de Lafollying, formerly the Director-General of Telegraphs, had brought before the notice of the *Societe d'Encouragement* some observations on the subject of the dry emulsion processes of M. Chardon. The negatives submitted on that occasion by M. de Lafollying in illustration of his remarks completely confirmed his views, and showed what excellent results could be obtained with this emulsion, for the plates were as fresh as those taken with the ordinary emulsions. M. de Lafollying urged very strongly that the practical photographer should be able to make the preparations he requires with the employment of ordinary chemical products only. In order to frustrate the curiosity of Custom House officials, and to obviate the inconvenience experienced by the tourist whose emulsions are accidentally exposed to light, he recommends travelling photographers to carry with them solutions of silver nitrate and soluble bromide in a highly concentrated condition, or even in the state of crystallized salts, and then to make the precipitate on arrival at the place of destination, for this will require only a little distilled water. "The emulsion which I made six months ago," continues M. de Lafollying, "by adding directly silver bromide to raw collodion, and had put on one side, remains almost in perfect suspension to the present day; it only requires a brisk shaking for a minute to bring it back to its original condition. The plate that I took had been exposed for a half minute in front of a triplet objective of 0.15 metre focal length, with a stop of a 0.01 metre in aperture."* Several members of the Society had followed closely M. de Lafollying's directions, but the results obtained were not satisfactory. In consequence of the numerous doubts expressed as to the efficacy of the process, the secretary of the Society had thought it right to ask M. de Lafollying to give some additional information; this he has now done to the perfect satisfaction of every one. Confirming M. Lafollying's explanations, M. Davanne, who presided on this occasion, informed the meeting that he had himself experimented in the same direction with complete success. His first attempts were made with raw collodion, and, notwithstanding the strictest attention to the prescribed precautions, he had not obtained satisfactory results, in consequence of the highly subdivided condition of the precipitates; some of these will not pass through the filter when the solutions are to a certain extent acid or

alkaline, and pass through, on the other hand, when this condition is modified.

Other Collodio-Bromides.—A number of plates taken by the collodio-bromide or dry emulsion process were shown at the meeting, and served to prove how regular and certain its results are. Very conspicuous among these were some taken in the Forest of Fontainebleau by M. Balaguy. This able photographer remarked that he preferred to increase the proportion of the reagents, and to make an emulsion by using in the collodion three per cent. of pyroxyline and three per cent. of the mixed bromides.

M. Ferrier's Method of Using Gelatino-Bromide Pellicle.—While speaking of the above process, it may not be without interest to mention a method given by M. Ferrier for working with a sensitive film or separate pellicle of gelatino-bromide. He places it between two thin glass plates, and introduces them together into the dark slide of the camera. Developing is effected as with ordinary glass plates; but in working, as may be easily understood, the greatest care is necessary, and the pellicle must be manipulated with exceeding caution. By this method M. Ferrier has taken beautiful prints, which he exhibited to the meeting of the Society of the 2nd of May, an account of which has already appeared in the PHOTOGRAPHIC NEWS. In perusing this account I note an omission of some importance of a subject of which the *Bulletin* testifies. M. Crefeld, of Cologne, had sent to that meeting a very remarkable portrait, proving that he has discovered a means of taking any number of impressions in fatty ink, and with the lithographic press, direct from the negative. Moreover, the negative can be kept and used at the same time for making copies in silver nitrate.

Photography with the Salts of Platinum.—To return, however, to the proceedings of the meeting of the 6th inst., M. Stebbing exhibited a collection of photographs in salts of platinum. With this method, he said, a rapidity could be obtained at least four times as great as that with the salts of silver. The manipulations are also much simplified; the plates are developed and washed, and that is all. It was also pointed out by M. Stebbing that a society for working the process was about to be organized in France, who would, he added, grant licences to use it at a price of one hundred francs to professional and fifty francs to amateur photographers. In submitting further some prints and negatives taken by the gelatino-bromide process, M. Stebbing mentioned that when intensifying the negative with silver nitrate, he had succeeded in preventing the appearance of the peculiar red, mahogany-coloured tint by the use of a bath of iron oxalate. All the specimens that he submitted really possessed a remarkably uniform colouration of black and white only.

German Prints in Fatty Inks.—M. Moulleron showed a superb series of prints taken in a fatty ink by M. Friseh, reproductions of the drawings in the fine collection of the Berlin Museum. This series came from Germany, and met with as much serious admiration as the letter of a photographer in Lubeck excited laughter; in the latter the author trumpeted forth, in a fashion all his own, his process for taking prints, the licence for working which in France he wished to dispose of.

A New Travelling Apparatus.—Portable apparatus for the use of tourists being now all the fashion, it is easy to understand that all the manufacturing firms of photographic appliances take a great deal of pains to produce one of which they have the exclusive right of sale. M. Vivien showed at the meeting an apparatus of his own invention, characterised by much elegance and simplicity. It weighs altogether barely four kilogrammes; the legs of the stand fold up in three, and, notwithstanding their lightness, are solid and strong. A novel kind of small winch serves to direct the instrument on the object with great precision. The special point in this portable apparatus of M. Vivien is the ingenious arrangement of the slide; this opens on both sides, and has two

* *Bulletin de la Societe Francaise de Photographie*, No. 125.

compartments for the plates, which can be put into place without touching them with the fingers, and also strictly in the correct position.

New Objectives by M. Steinheil.—Some new objectives by M. Steinheil, and especially intended for portraits, groups, landscapes, and reproductions, were exhibited by M. Carotte, who is the sole agent in France for this maker. These objectives are very fine, and beautifully finished; but an observation with regard to them made by the President was received with general approval. It is much to be regretted, he said, that the manufacturers will use so much brass in the construction of their instruments. Without the instruments we are already overladen on a journey, and it is much to be desired that some ingenuity could be shown in diminishing the weight of the objective. There is no necessity to be so careful of the appearance of an instrument, which is all the advantage that so much casing in brass possesses, unless it be that of increasing the cost.

New Photographic Works.—A curious specimen of litho-photography was next submitted to the meeting to delight the eyes of the members. It is a book with the title *Reproduction Heliographique de l'Essai sur les Gravures Chimiques en Relief*. There may be a risk of its being confounded with a publication with a similar title, the work of M. Motterez. At first sight it might easily be mistaken for a printed book, and it requires close examination to convince one that we have here another triumph of photography; in this case our art has really done wonders. This charming publication, together with a book of Mr. Huberson, entitled *Formulaire Pratique de la Photographie aux Sels d'Argent* are the greatest novelties in the photographic book line.

The Subscription in Aid of the Monument of Niepee.—At the same meeting there was announced the amount of the subscriptions collected by the Photographic Society of France for the benefit of the monument to be erected in memory of Nicéphore Niepee. The total of these subscriptions amounted to the sum of 5,625 francs 30 cents—a sufficiently paltry figure. The offensive partiality shown by the committee at Chalons-sur-Saone, which I have mentioned in previous correspondence—a partiality for which the Photographic Society is in no way responsible—is no doubt the cause of a want of enthusiasm on the subject of the monument. Only two days before the amount of the subscriptions was published, the violent attack on the memory of Daguerre was for a second time the subject of discussion at a meeting of the Photographic Union of France. All the members present were unanimous in resenting the accusation as one which is as unjust as it is inopportune, and after a most interesting discussion a letter containing a strong protest, which had been drawn up by the officers, was approved with acclamation. An application has been also made to the municipal authorities of Corneille-en-Parisis asking them to take the initiative in a movement for erecting a monument to Daguerre. In a former letter, relying on certain biographies, I stated that Honfleur was the birthplace of Daguerre; it is now, however, agreed that the illustrious co-inventor of photography was born in the above-named Corneille-en-Parisis, a small place near Argenteuil, in the environs of Paris. Doubtless nothing concerning the history of photography can be indifferent to the readers of the PHOTOGRAPHIC NEWS; I therefore propose to devote an article to an explanation of the respective shares which Niepee and Daguerre each had in bringing to perfection an invention which the world pursues with so legitimate an interest. To falsify history is at any time a grave offence; how much more so when illustrious men like Arago, Gay-Lussac, Chevalier, and many others besides, have exerted their great authority to promote the public homage rendered by the French Government to the two inventors conjointly, in making them a grant out of the public funds.

K. VERSNAEYEN.

HOW TO ESCAPE A BREACH OF PROMISE ACTION.

A CORRESPONDENT sends us the following:—

"The other day a muscular young fellow, having an odour of the stables about him, entered our studio, and explained that he would like to have one C.D.V. taken. After a little parley as to the proper price to be paid, he took his hat off and roughed up his hair. When he sat down he shut up one eye, drew his mouth around one side, stuck up his nose, and patiently awaited my commencing.

"'Good gracious!' said I, 'you do not want to be taken in that manner; nobody will know you from Cetewayo!'

"'You go a-head,' said he.

"'Do you really want me to take such a phiz as that?'

"'I do.'

"We took it. The photograph beat anything we had ever seen, and was highly satisfactory to the sitter. As he paid for it he said—

"'You see, I had a sort of object in this. I come from Birmingham just six months ago, engaged to a girl out there; I have found another here I like better, and so I am going to sever old ties, &c. See?'

"'No; I don't see what the picture has got to do with old ties,' I answered.

"'Lots—heaps! I've writ her that I was in a railway collision and disfiggered for life. You see she's proud, and when she gets this and sees how that explosion wrecked me, she'll hunt up another lover quicker'n wiuk. See? How do you like the plot? Just gaze on that picture once, and then tell me that Polly won't send back my letters by first mail!'

"He sealed the envelope. The letter was brief, but to the point. It said: 'My Evver Dear Polly—I incloze my piktüre, that you may see how oful bad I was hurt, tho' I know you will luv me all the same.'

"'Ever see this game worked afore?' he said, as he licked the stamp.

"'No; never did.'

"'Course you never did; it's mine. It struck me the other day when doing a hoss. Collision. See? Disfiggered for life. See? Picture enclosed to prove it; and she'll write back that she has at length concluded to yield to her parent's wishes, and not marry me, but another fellow who owus a cab of his own.'

"RODERICK RANDOM."

MY EXPERIENCES WITH GELATINE PLATES.

BY H. GARRETT COCKING.*

AS Solomon says that "there is nothing new under the sun," possibly difficulties in working gelatine plates may have gone through thousands of years ago. But as I found we had only one paper for this evening, I thought, perhaps, a few words on the subject of gelatine plates might produce a good discussion.

I must begin by saying that, prior to two months ago, I had not had any experience with dry plates of any sort, and have always believed in the wet process as being the best suited for the professional portrait photographer. Two months ago I first tried the gelatine plates. Having stopped out all the light from my dark room, and having reduced the window to about three inches square, I began to work. I exposed a plate, but did not get the ghost of an image. Thinking that perhaps I had underexposed, I gave a longer exposure, and got nothing. After repeated trials I succeeded in getting some faint trace of the image, and, strange as it may appear, the only negative that could possibly be printed from was exposed forty seconds.

Well, not having either the time or the inclination to keep on experimenting, I thought I would accept a kind invitation I had received from Mr. W. Cobb, and take my woes to him. Accordingly I took some of my bare glass

Read before the South London Photographic Society.

(for you could not call them negatives) down to Woolwich; but Mr. Cobb even was unable to account for my utter failure, and so am I to this day. I saw Mr. Cobb take some negatives, and he very kindly demonstrated the whole working of the process to me. The next day I began again on my own account.

The first sitter being that day a baby, I employed a dry plate, and as a necessity gave a very short exposure, the result being an excellent negative. Since then I have never met with the same failure I at first experienced; but why a long exposure should have succeeded in my first experiments, when, as it would appear now, that short exposures only lead to success, I am quite at a loss to account for.

So much for my first experiences. Now for a few of my later ones. First, I had to consider the matter of getting a better light to develop by. I procured some of the ordinary orange paper and pasted my yellow glass over. Finding the light still weak, as my dark room window is small, I well oiled the paper, and found that I then had a very good light to work by. I have brought part of my window with me to-night, so that you can judge of the amount of light admitted. I find it answers just as well in front of artificial light. The sun, when it shines—which, I am sorry to say, has not been much lately—does so in the afternoon direct on to my dark room window; but I have found as yet no trace of fog.

The greatest difficulty I find with gelatine plates is in getting sufficient density if the plates should happen to be a trifle over-exposed, and when a second makes a vast difference it is a matter of some difficulty to hit the right exposure. A little more ammonia added to the developer will secure this, but I find it also acts upon the shadows, and still the negative prints up flat.

I think, perhaps, I work in rather too much of a hurry. I mean that it seems to me we do not keep the developer on long enough. I do not know if other wet-plate workers have found the same result, but I imagine that directly all the detail is visible we must stop the development. Now, I have found that by developing slowly and keeping the developer on a long time much greater certainty may be obtained in the density; therefore I think the best plan is not to develop the negatives at the time of exposure, but leave them till the latter part of the day or evening when you are not hurried, which is the case when sitters are waiting.

Another thing is that the ammonia acts upon the negative bath when worked in the same room. Mine, a few days after using ammonia in the dark room, gave nothing but pinholes, and, as I still occasionally use the wet process, I have had to have another dark room built to work it in.

I have also brought a few prints and negatives with me. They are nothing very grand; but, only having been at the work two months, I think they may be taken as being an evidence of the right way having been entered into. I may mention that the children are all taken as nearly instantaneously as possible.

My principal object in bringing before you these few experiences is this: that possibly many in far-away places may, meeting with similar difficulties to those I have alluded to, and not having the benefit of conferring with those whose previous success would lead them to suppose that some benefit might be gained by conferring with them, may derive hope from the well-known proverb—"Perseverance overcomeeth obstacles."

I think I will now close, hoping that some of the older workers may have something to say upon what I consider one of the greatest wonders of modern photography—gelatine.

PS.—Since writing the above, I have had my new dark room finished. I have mentioned in my communication that soon after beginning to work the gelatine plates the ammonia upset my bath, which gave pinholes to a fearful extent. Not having another room convenient, I set about building one, which was finished on Tuesday. Knowing

that my bath gave such awful results, before I tried it again I placed some nitrate of baryta in the bath, and immediately the pinholes vanished, and every plate worked well. I merely mention this fact that any one encountering the same difficulty as myself may at once cure it in the same way. I do not know the quantity of solution in my bath, but it is an ordinary 10 by 8 glass dipping bath full, to which I added ninety grains of nitrate of baryta.

Correspondence.

DRY PLATE WORK IN THE STUDIO.

DEAR SIR,—When you published my letter on the 9th ult. I was quite unprepared to face the enormous personal correspondence which has since ensued in reference to the use of dry gelatino-bromide plates in the studio. I thought that my reply through you the following week would have set the matter fairly at rest. But no; still they come from all quarters, and in such quantities that personal reply is simply impossible without the assistance of a very smart secretary, not to talk of stationery and stamps for between six and seven hundred letters.

I am asked over and over again questions I answered in your issue of the 16th May, to which correspondents will kindly refer. One point I certainly overlooked, that of the healthiness of dry plate work; and all who have made enquiries on that point may rest assured that it is far before collodion. For my own part, I was very seldom free from headache (sometimes very severe) with nausea after the day's collodion practice; but since adopting dry plates I seem to live a new life, headaches have vanished, my work is a pleasure, and the worry of business reduced to a minimum. I believe this to be the experience of every successful dry plate worker.

A month since I had no idea of entering the commercial list, and within that time I have been simply forced into it through the earnest and pressing applications of numerous correspondents anxious to be supplied with good plates and emulsion, and get well started in dry plate work. This has compelled me to abandon—at least, for the present—the giving of practical instructions in the making and use of dry plate material at photographers' own establishments, which I at first consented to do, and which has been a very pleasant duty indeed so far as it has gone. I can now only hope that simplicity of printed instructions in working a simple system will enable all our clients at a distance to succeed perfectly with this queen of photographic processes.

—I remain, dear sir, yours, &c., W. H. NELSON.
Twickenham, S. W.

ELECTRIC SHUTTER.

DEAR SIR,—If any of the readers of the PHOTOGRAPHIC NEWS who have had any experience with an electric shutter which was extensively advertised last year would be so good as to inform me by post as to their opinion of its merits or demerits, I should esteem it a great favour, as the information would be of considerable use to me if received *not later than Monday next*.—I am, sir, your obedient servant,
G. WATMOUGH WEBSTER.

19, Bridge Row, Chester, June 10.

BEECHEY EMULSION.

DEAR SIR,—I find that if the bottle containing the collodion is warmed by immersion in hot water, before flowing the alcoholic solution of silver into it, the resulting emulsion is much smoother, and there is an entire absence of those clots which sometimes make their appearance in this otherwise faultless process.

Your correspondent of last week, "Content," is not half lazy enough: he ought to employ someone to push his "Salvo-Quadricycle" for him, who might develop his plates on his return home. The same party might perhaps expose the plates, so as to take all the bother and trouble off "Content's" hands.—Yours truly,
R. GORDON.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on Thursday, June 5th, at the Society of Arts, John Street, Adelphi. The Rev. F. F. STATHAM, M.A., presided in the chair.

The SECRETARY read the minutes of the last meeting, which were confirmed. Mr. S. W. Rouch was elected member of the Society.

The CHAIRMAN said that he was pleased to see two of the younger members coming to the front by reading papers; he thought that was a good augury for the future of the Society. He remembered years ago that some had come forward with papers in a very humble way, and gentlemen that were still members of the Society, and now were ornaments to the profession, which was very gratifying to see. He then called on Mr. Brittlebank to read his paper "On the Future Usefulness of the Society" (see page 278).

The CHAIRMAN said that he felt sure that all must agree with the paper they had just heard read, but at the same time it was rather a difficult subject for the Society to deal with practically. He had an idea that in years past something similar had been introduced or proposed by some other member, and he was of an opinion that it won't do a great deal of good to novices or younger members of the profession; but the great difficulty was that it would require a certain amount of capital which a society like this had not at its command, and he was quite sure if it was possible to carry out the idea it would greatly improve the knowledge and taste of its members.

Mr. FOXLEE said that the Society of Arts, he thought, had something of a similar kind, so that members of the profession could pass in the different grades.

Mr. E. COCKING said that he understood that what Mr. Brittlebank meant was to establish a purely elementary class; in the one just alluded to money prizes were awarded.

Mr. BRIDGE said that he remembered something of the same kind being proposed, but the question was, who was to pay for it, as it was impossible for the Society to think of such a thing, as he might say that we had no home of our own.

Mr. FOXLEE said there was a class for photography already in existence at King's College; it was formerly under Mr. F. Hardwick; also one was held at the Polytechnic, Regent Street.

The PRESIDENT remarked that if such an affair was established, it ought to be established on a commercial basis.

Mr. BRIDGE said that he remembered, some years ago, that a class in connection with a Musical Society was established, but the only way the society was able to carry it out was to have it open one whole week or more in the year, and engage the best professors possible; and then pupils came from all parts to study, such as governesses, teachers, &c. They came up for the week or ten days, and stayed the whole time; and he had no doubt that many derived a great benefit from such a course of instruction.

Mr. FOXLEE thought it would be impossible to devote any evening out of the Society's meetings to such a purpose, as we had only eight business meetings in the year, and practical members would take no interest in meetings of such a character.

Mr. G. COCKING (the Secretary) then read a paper, "Experience with Gelatine Plates in the Studio" (see page 284). Specimens were handed round.

Mr. BRITTLEBANK said that he had found the same thing occur after developing gelatine plates in the dark room; that his ordinary negative bath for the wet process gave pinholes.

Mr. FOXLEE said that he could not conceive how pinholes could be produced by ammonia fumes in the dark room; he should think that it was owing to the increase of temperature during the last few days.

Mr. CLARKE said that he had noticed that his bath, after a day's rest from Saturday till Monday, often gave pinholes.

Mr. FOXLEE, alluding to Mr. Cocking's failure in not getting an image, said perhaps Mr. Bennet's theory might explain, as he stated that over-exposure gave a positive image, and a greater exposure gave again a negative image, and it might be between these peculiar changes that he was unable to obtain a result.

Mr. A. COWAN handed round for inspection some charming cabinet negatives taken on gelatine plates, also some prints; he said that most of them were taken with one or two seconds' exposure, and he might state that he could get plenty of intensity by first commencing the development with a six-grain pyro solution instead of a three-grain as recommended, and then adding a few drops of the ammonia and bromide solution; this gave a feeble image, which was then finished off. With the full dose of ammonia and bromide

it was always best to get too much density than not enough, because the former could easily be reduced, whereas the latter had to be intensified, which was not altogether satisfactory. With the bromide and ammonia solution he used it diluted, so that when the pyro solution, that was six grains to commence with, at the finishing was only about two grains strong. He had developed a great many plates by this system, and had been very successful. He had developed as many as five in a dish at a time. If all were exposed alike, all came up alike. He considered now to develop a gelatine plate was a very simple matter.

Mr. HAZARD also handed round some very fine landscape specimens taken on gelatine plates, which were greatly admired.

Mr. PAYNE JENNINGS said that he should like to know a good reliable intensifier for gelatine plates, as it seemed almost impossible to judge as to density in the dark room, the plates being so opaque.

Mr. COWAN said that he judged the intensity by the time they took in developing (of course his experience was in the studio), but if the exposure was right there was not any difficulty; but plates by different makers varied very much indeed.

Mr. Wm. BROOKS said that some time ago he developed some commercial plates, which were very dense indeed, so that the true density could not possibly be seen; but on fixing, the image vanished to a mere phantom, which was perfectly useless. The films before exposure were as dense as a deal board.

Mr. LAVENDER said by what he had heard this evening it seemed that a machine could develop a dry plate now.

Mr. YORK said what was wanted was some means of local intensification; if that could be discovered it would be very useful.

Mr. PAYNE JENNINGS was of the same opinion as Mr. York.

In response to a question put by the Chairman,

Mr. COWAN stated that his experience with dry plates in the studio dated from October last; and

Mr. HAZARD said that he commenced the use of gelatine plates about the same time.

A vote of thanks was then passed to the gentlemen who had contributed to the evening, and the proceedings terminated.

The PRESIDENT said that he should be pleased to see all the members at his house on the last Saturday in July, as usual.

It was proposed to hold the out-door meeting at Highgate the last Saturday in August, but particulars would be duly announced after arrangements had been made.

PHOTOGRAPHIC SOCIETY OF FRANCE.

MEETING of the 4th of April, M. PELIGOT, Member of the Institute, in the chair.

The announcement having been made in one of the scientific journals that the Vicomte de Verguet-Lamotte, a well-known vintgrower, had discovered a method of analyzing wines by means of photography, the Secretary wrote to ask for particulars, and received a reply from which it appeared that M. Lamotte has been in the habit of examining various kinds of wine with the microscope, and also making microscopic preparations of the same; of some of these latter photographs had been taken, and this was all the foundation for the erroneous statement.

A letter was read from M. PAUL GAILLARD offering a sum of five hundred francs for the foundation of a prize to encourage photographic research, and begging the executive committee of the Society to draw up the conditions for the competition.

Among the articles from foreign journals brought under the notice of the meeting was one from the PHOTOGRAPHIC NEWS containing Mr. Houlgrave's formula for decreasing the proportion of gelatine in emulsions.

M. FERRIER observed that he had met with the same difficulties as Mr. Houlgrave, and had obviated them by adding to the emulsion a little non-emulsified gelatine. He had also found that in whatever way chrome-alum was used, it always acted as a retarder.

Apröpos of the discussion which arose in the Photographic Society of Great Britain on a communication from Mr. Berkeley as to the employment of opaque gelatine,

M. STEBBING remarked that Mr. Kennett expressly recommended the use of that kind of gelatine. He added that a test of the goodness of gelatine is its non-precipitation by acetic acid.

M. ROOZER was of opinion that all kinds of gelatine gave good results. He had made emulsions with the glue called *colle de Givet*, and had obtained results as good as those with the finer and more expensive gelatines.

M. FERRIER observed that anyone who wished to have a gelatine of uniform quality should use fish-glue, a natural product, very constant in character.

M. CHARDON had tried from twenty to thirty specimens of gelatine, and had found that neither the fineness nor appearance

of the sample gave any indications of its photographic qualities; those depend rather on its being tough or tender. The hard or tough kinds are very good, while the tender ones give rise to blistering, which can only be got rid of by treating the gelatine previously with alum.

M. STEBBING laid on the table some packets of dry gelatino-bromide, and expressed a hope that it might be tried by the committee appointed to report on dry processes; also a bottle of iron oxalate developer whose formula was somewhat different from those hitherto published. This developing solution, he said, might be used for an indefinite period, provided it were kept in the dark. The plate must be left in the bath until, on looking at the face, the high lights made their appearance. It is then finished, and requires to be only washed and fixed. As with the use of this bath a great latitude in the length of exposure was admissible, success would be certain; only the shorter the exposure the longer the development.

M. GOBERT had tried the developer, and was able to corroborate all that M. Stebbing had said of its good qualities. He inquired whether it was equally adapted for collodion emulsions.

M. STEBBING replied that it is not so suitable for collodion; he had found, in this case, the alkaline developer much better. In reply to other questions, M. Stebbing added that for preparing an emulsion with the pellicle, of which he had placed samples on the table, he employed the following formula:—

Pellicle	10 grammes
Water	110 "
Alcohol	5 "

The pellicle is dissolved over the water bath at a temperature not exceeding 40° C. To coat the plate (which must be warm), he uses a pipette in the shape of a narrow funnel, which he fills from the top with the gelatine solution, keeping the lower end closed by the finger; in this way any bells which may show themselves in the upper portion can be easily removed. Now, removing the finger, he allows the solution to flow over the plate from the centre outwards, and distributes it either with the finger, or with a glass rod. So soon as the gelatine is set, he places the plate to dry on the shelves of his laboratory.

M. FRANCK DE VILLECHOLLE observed that gelatine in the form of pellicle is more sensitive than when it has been kept for a time without undergoing desiccation.

M. CHARDON laid before the Society the results of his further experiments with collodion made from Russian cotton wool (see account of the proceedings of the Society in PHOTOGRAPHIC NEWS for April 10, p 179). The collodion prepared according to the formula then given was found so porous that the negatives produced with it were too soft, and could only be intensified with great difficulty, defects which he now attributes to the high temperature, 85° C., to which it was submitted. In his more recent experiments, having a larger supply of the cotton, he had been able to make two kinds of pyroxyline—the ordinary and the precipitated. The first experiment was made at a temperature of 60° C., which was found to be too low, as the mixture of potassium nitrate and sulphuric acid remained in a pasty state, and the cotton could not be well immersed in it; with a temperature of 65° C. he succeeded better, using the following formula:—

Sulphuric acid	1000 parts
Potassium nitrate	500 "
Cotton	25 "

The cotton was left in this mixture for five minutes, then taken out and thoroughly washed in water until no trace of acid was left. Of this pyroxyline M. Chardon dissolved one hundred grammes in two litres of alcohol and four litres of ether, and left the solution to stand for sixty hours; he then decanted, and precipitated the pyroxyline from the collodion thus prepared. He prepared the bromide emulsion with 6.5 per cent. of the precipitated pyroxyline, but found that the film made with it was poor, and that the plates remained very transparent. This he attributes to the steam at high pressure to which the cotton is submitted in the preliminary stage, in order to get rid of the resinous particles; this attacks the fibre, causing the pyroxyline to be very porous and wanting in cohesion, so that the silver bromide is not properly retained in the emulsion. In conclusion, he was of opinion that there is no advantage obtained by using this kind of cotton in the emulsion processes. He was not aware whether it would have the same results in the wet collodion process, but all the facts led him to think so.

M. ROGER submitted to the meeting some negatives taken with gelatino-bromide after the formula of M. Ferrier. No importance was attached to the kind of gelatine used, though, as a matter of fact, all the sorts experimented with were transparent. M. Roger highly praised the gelatino-bromide process on account of its

simplicity and the ease with which the emulsion is prepared: the only tiresome and difficult part of the process is in the drying. For this he recommended a drying box made of soft wood, with sliding shelves of rather smaller dimension than the box itself, and so arranged that a current of air could be made to pass all round and between them. If this box be placed over a warming-pan or hot water plate, the plates will be dry in a few hours. Or a draught may be set up by means of a chimney flue on the top of the box, in which a night light is kept burning, taking care that the air before admission is dried by being made to pass over calcium chloride, or pieces of pumice moistened with sulphuric acid. When heat is used it must not be too great, or on dipping the film in the solution of hyposulphite it will crack in all directions. Also before flowing the gelatine over the plate the latter must not be too warm, or bubbles will form and spoil the film.

M. DAVANNE, in behalf of Mr. Woodbury, exhibited some specimens of paper as transparent as glass, to be used for transferring negatives. On another occasion Mr. Woodbury proposed to make a further communication on the subject.

M. STEBBING remarked that lithographers were in the habit of using a paper which, as far as transparency goes, was very similar to that exhibited; and

Capt. JOLY stated that paper when treated with copal varnish becomes quite as transparent as that of Mr. Woodbury.

Several members believed that paper which has been coated with a resinous varnish has the inconvenience of soon turning yellow, which would be a grave defect in the case of negatives.

PHOTOGRAPHIC SOCIETY OF BERLIN.

At the ordinary meeting on the 17th April, Herr C. BRASCH in the chair, a lecture, with experimental demonstrations, was given by Herr E. DUBY, on the "Services Rendered by Photography to Science." These services, he said, divided themselves naturally into two classes:—(1). As regards the photographic recording of scientific observations; (2) the use of photography for illustration and demonstration. As instances of the former, Herr Duby referred to photographs of the spectrum, where measurements could be effected with the greatest accuracy, and to micro-photographs, which permitted of a much more extended and less fatiguing examination than was possible of the actual objects under the microscope. Of the second class, he adduced the great benefits conferred on the art of projecting with the lantern by the employment of photographic slides; what previously was nothing but an amusing toy had by this means become an important vehicle for conveying knowledge. This part of his subject Herr Duby illustrated by projecting on the screen, with the aid of the oxy-calcium light, a number of transparent photographs by Herr Ganz, of Zurich. This well-known photographer was stated by the lecturer to have devoted himself to the preparation of photographic slides for the lantern for educational purposes; among them are diagrams and pictures illustrating anatomy, physiology, botany, and zoology; architecture, astronomy (fixed and movable slides), geology, and physics, &c., all executed in carbon printing, and some coloured. The lecturer then spoke more especially of the applications of photography to astronomy, and explained the principle of construction of astronomical telescopes, illustrating his explanation by the exhibition of views of the more important telescopes at the Paris and other observatories. He described also the arrangement of the photo-heliograph and photo-siderograph, explained the method of correcting any difference of focus, and projected on the screen pictures of the celebrated instruments of Padre Secchi and Mr. Browning. Lastly, the results of photographic astronomy were treated of, and illustrated by the projection on the screen of photographs of the solar protuberance, of the planets Jupiter and Saturn, and also of some very excellent ones of the moon by Rutherford.

At the subsequent meeting on the 1st May, Herr DUBY delivered the concluding portion of his lecture. On this occasion he referred more especially to photography as a registering agent, and mentioned its use in this quality in different branches of science. He described the photographic apparatus for automatically registering the height and variations of the tide, also the barograph, thermograph, and psychro-thermograph for registering the atmospheric pressure and temperature and the hygroscopic condition of the air. The photo-sphygmograph, an instrument for reading the pulsations of the heart, was also briefly referred to, as well as other medical instruments—laryngoscope, ophthalmoscope, otoscope, and methroscope—in all of which photography is used as the registering agent, and a number of photographs illustrating their uses and capabilities were handed round.

After the lecture, Herr G. KLREFFEL, the agent in Berlin for Messrs. Wratten and Wainwright, exhibited some views of the Oxford and Camoridge boat-race, taken on their gelatine emulsion plates of that firm. The exposure was stated to have been of two seconds' duration, and, considering the foggy climate under which the views were taken, the result was regarded as wonderful. They are cabinet size, and the lens used was a D by Dallmeyer, of 12 inches focal length, with a $\frac{1}{8}$ stop.

A very lively discussion ensued on the gelatine emulsion process, and on the development of the plates after exposure. By the use of pyrogallic acid the gelatine film is partially tanned, which considerably retards the development; but, according to Herr Brasch, this difficulty can be avoided by employing potassium oxalate, or iron oxalate, as a developer.

Herr FRICK, jun., showed a couple of plates representing transparent positives taken directly. According to his own account, he collodionizes and silvers a plate as in the ordinary process, rinses it thoroughly with water, and then flows over it a particular kind of organic acid, from which it acquires the property of giving under direct exposure in the camera a transparent positive instead of a negative. The plates which were exhibited bore every evidence of being really positives; but they were generally pronounced to be wanting in transparency, and in that sharp contrast of light and shade which gives a transparent positive all its fresh look. The attention of the meeting was also drawn to the fact that the subject of direct positives was very fully treated by Dr. Schnauss in the *Photographische Wochenblatt* of last year (see PHOTOGRAPHIC NEWS for March 29, 1878, p. 119).

Talk in the Studio.

PAINTING ON CHINA.—The history of photography has often given contradiction to the commonly repeated assertion that genius or ability is not hereditary. It is by no means uncommon to find the sons of distinguished photographers treading close upon the heels of their fathers, and worthily maintaining a good reputation. An interesting illustration, in a varied form, may be found by our readers who may be sufficiently interested in good painting on china to visit the exhibition now open at Messrs. Howell and James' galleries in Regent Street. No. 201 is a charming painting entitled "Puck," which is very highly commended by the judges, who are Royal Academicians. This painting is by Miss Edith Robinson, eldest child of Mr. H. P. Robinson, with whose artistic abilities all photographers are familiar. This young lady worthily maintains the artistic traditions of the family.

To Correspondents.

A. C. B.—Negatives may be treated with a solution of albumen, but it will not be nearly as perfect a protection as varnish. It will more easily scratch, will be affected by damp, will probably stick to albumenized paper in printing, will stain, and subject to mould, mildew, and decomposition. 2. Some photographers, after retouching upon matt varnish, re-varnish with a hard varnish. But much depends on the nature of the matt varnish. If it be composed of gum-resins, soluble in the second varnish, it would not be safe to apply a second varnish. 3. The cause of newly iodized collodion quickly acquiring a deep colour is the liberation of free iodine, and this generally arises from the presence of a little acetic ether in the ether employed. The cause of the rapid loss of colour, again, is not so clear; it has been ascribed to the presence of a bromide. Our impression is that some alkaline impurity has been present, like carbonate of potash or ammonia, which, combining with the iodine liberated, removes the discolouration.

GREEDY.—Mr. Hardwich's book was entitled a "Manual of Photographic Chemistry." The last edition was edited by Mr. Dawson. The work which Mr. Sutton and Mr. Dawson issued conjointly was an edition of Mr. Sutton's "Dictionary of Photography." In our estimation, Captain Abney's Instructions is quite as useful as an aid to the study of the chemistry of photography. 2. The forthcoming work of Mr. Robinson, being a new edition of his "Pictorial Effect," will be presumably in advance of the former edition. It will be issued at a lower price.

E. K.—A brilliant purple tone is only to be obtained by a conjunction of things all in harmony. A good brilliant negative, a good sample of albumenized paper made sensitive on a silver bath of proper strength suited to the paper, moderately deep printing, and a toning bath in proper condition. Almost any of the toning baths in use will serve, but there is none better than the acetate bath for the purpose. But the negative must be a good one, with sufficient intensity.

J. B.—The coffee process, as described in our YEAR-BOOK for 1877, is one of the simplest and best dry processes we know; but all bath processes are passing away amongst dry-plate workers, emulsion processes taking their place. The emulsion process described by Mr. H. Cooper in our last issued YEAR-BOOK is a very good one. So far as we know, all the emulsion plates at present in commerce are good; but we have no means of determining which are best. It is not difficult to try. Obtain a packet of any of those you see advertised in the NEWS, and if you follow instructions carefully, we have no doubt that you will succeed. 2. It is quite impossible to answer with precision your second question, as to how much hypo is necessary to fix half-a-dozen sheets of albumenized paper. Fixing means dissolving and removing the unchanged salt of silver in the paper, and the proportion of silver salts varies with the strength of the salting solution of the silver bath, also with the kind of picture. In a vignette, for instance, there is twice as much unchanged silver salt to be removed as there is in a portrait printed-out. If you can estimate the amount of chloride of silver in your print to be removed in the fixing process, you may form some idea. Chemically estimated, three parts of hypo are required to dissolve one part of chloride of silver. It has been estimated that one sheet of paper contains from 25 to 30 grains of chloride of silver, which would require from 75 to 90 grains of hypo, or about an ounce for the half dozen about which you enquire. But remembering the frequent presence of free nitrate as well, and other varying conditions, a prudent man will use three or four times as much hypo as the amount indicated. As a rule, about four ounces of hypo in a pint of water. Many photographers make a similar complaint that their pictures of late years are less permanent than were their prints of earlier years. We cannot explain the cause, although we have at times devoted articles to consider the possible and probable causes.

A. C. S.—The work by Lake Price to which reference was made was published some years ago by Churchill and Co., entitled "A Manual of Photographic Manipulation." It was not a reprint of any previously published papers. The papers in the NEWS by Lake Price on Composition and Chiaroscuro were never published in a separate form. Mr. Robinson's papers on Pictorial Effect which appeared in the NEWS were subsequently published in a separate volume, of which a new edition will shortly be issued. We will bear in mind your suggestion as to the publication of a selection of papers from the NEWS, and give it due consideration.

J. B. L.—A very dense negative is best printed in direct sunlight, which will penetrate those semi-opaque portions more perfectly than diffused light, and give a softer and more detailed print. Print, on the other hand, a thin soft negative, in diffused light, if you wish to secure a brilliant print. A somewhat weak toning bath is safer than one which is too strong.

CAPTAIN WATERHOUSE.—We believe it is not yet in the market. We will make further enquiry, and endeavour to send you early sample.

PRESSURE FRAME.—Captain Abney's Instruction Book contains much information on the chemistry of photography. 2. You ask what causes chloride of silver to blacken when exposed to light? We might, in reply, ask what causes fire to burn or water to flow? Perhaps it may help you better if we say that the chemical action of light has a tendency to liberate the chlorine from the silver, which is left as a black metallic powder. 3. The chloride of gold in the toning bath is decomposed, chlorine set at liberty, and metallic gold deposited, which, in a finely divided state, is purple.

2ND D. C. R. V.—We regret that your question is one which we cannot answer satisfactorily. We cannot, with propriety, undertake the invidious task of mentioning in these columns one maker of dry plates as superior to another; and if it would be right to do so, we could not, as we have never made comparative trials. We have seen very fine results on almost all the commercial gelatine plates. We believe there are none absolutely certain, as all must depend on the treatment they receive. But with care to follow instructions, we believe most of them are trustworthy.

AMATEUR asks the best way to "dry gelatine with potash for making blocks." We are really puzzled as to the meaning of his question. He also asks if he "can take impressions of gelatine in asphaltum for rubbing down on round surfaces for etching." Here also we are puzzled. What are the impressions in gelatine to which he refers, and how are they to be taken in asphaltum? We do not know any work on the subject.

J. TERRAS.—Your studies are very interesting. How far it would be worth your while to publish them, we cannot say; not because they are not pretty pictures and excellent photographs, but because the demand for such things is not great.

J. W. H. ANDERSON.—We should say that the most suitable for rapid work is that you mark B. Your statement as to the permanency of Carrier's paper is very interesting. We do not know whether it is prepared or not now.

R. SYMONS.—Your photography of mirage received. The interesting letter in our next.

The Photographic News, June 20, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AND PHOTOGRAPHERS AT CYFARTHFA CASTLE.—WITH the late Mr. Crawshay's death, Cyfarthfa Castle ceases to be the home of an "iron king." For the matter of that, as our readers know very well, it is some years since Mr. Crawshay's huge iron works were in full operation, and one of the reasons why he devoted so much of his time latterly to photography was that his principal object in life—to be an active ironmaster—had passed away. We do not mean to say that he did not commence as a photographic amateur until the management of his iron works ceased to make calls upon his time, for Mr. Robert Crawshay was always a busy man; but to photography he turned with renewed energy as his leisure increased. Another reason for his devotion to the camera was the fact that it offered a great solace under the deep affliction from which he suffered. Of late years he was so deaf that no sound could be appreciated by his ear, and he either read the expression of one's face, or words rapidly written down for his behoof. Living, therefore, in a silent world by himself, it is no wonder that he appreciated camera work, and the possibility by its means of depicting the beauties around him. So imbued did he become with the charms of photography that he ceased to regret (or, at any rate, appeared to do so) the grand—one might almost say royal—position he had held like his fathers before him. Four generations contributed to build up the fortune of the Crawshays; as feudal baron and patriarch, the reigning house of Crawshay cared for their people as a father watches over his family. The master's sons served their time and worked with the humblest at the works, and an honest workman, if he could not get justice done him in any other way, made no difficulty about seeing the master, and placing his case before that high tribunal. It was the Trades Union that broke up this friendly relation between master and men, and it "blew out" the furnaces that had been burning for generations. But, for all that, the late Mr. Crawshay never spoke ill of the Union. "Why should I?" was his argument to a deputation of workmen, who, a few years back, asked him to light the furnaces again, and call up the old times once more. "The Trades Union has been to me my best friend. It caused the men to strike, and enabled me to close my works, which I was carrying on at a loss. By the Union I have gained—or, rather, been secured from the loss of—a large sum of money. But you closed the works against my will, and thus for ever annihilated the friendly spirit that existed between us. In future it is only a matter of business between you and me, and I frankly tell you it will not pay me to work my iron at a loss." Such was the substance of Mr. Crawshay's final address to his men, when he gave up his sceptre as the iron king; since then Cyfarthfa Castle held but a dethroned monarch. But if he ceased to be foremost among British ironmasters, he speedily won renown as an art-photographer. His magnificent life-size portrait sketches taken direct in the camera won him honours in this country and elsewhere; while his generosity, when it was a question of fostering art, is widely known. He wished to see photographers get out of the narrow groove into which they had fallen since *carte-de-visite* portraits came into vogue. *Cartes* and cabinets are very well in their way, but Mr. Crawshay believed he could improve photographic art by directing it into broader channels and encouraging the depiction of larger portraits. And there cannot be a doubt that the encouragement afforded by the munificent prizes he offered for large work materially influenced photographers to abandon the narrow limits that previously entangled them. Whether heads of extreme size, measuring eight or nine inches, present the most favourable pictures or no, certain

it is that their production has taught the photographer many practical lessons; while the size (four or five inches) for which the second series of Crawshay prizes were offered is universally admitted to be one of the most charming and effective forms of photographic portrait. Mr. Crawshay by his encouragement and example may be said to have shown what is possible and impossible in the matter of large photographic portraits; and when in later times he began to turn special attention to landscape work, he proved himself an adept in this branch of the art. When offering his second series of prizes for portraits, it was suggested to him that landscape photography might also be benefitted by encouragement of the same kind, and without hesitation he at once placed £50 in the hands of the judges to be distributed for this purpose. This, indeed, was but one instance of the readiness with which he was willing to aid the photographic art and photographers. A series of sketches of a deceased photographer that were for sale was brought to his notice by a friend, who desired to raise money for the widow. "What shall I give for them?" he asked, and the amount suggested was at once paid, and received with thankfulness by the widow. If he had confidence in the application, or the person that made it, Mr. Crawshay was ever willing to give; but he was just as ready to turn a deaf ear to many doubtful claims, such as are always being made upon a rich man. His spontaneous invitations to spend a week or a month at Cyfarthfa Castle were extended year after year to a group of gentlemen connected with photography, and as a generous host he spared no pains in making his visitors welcome and comfortable. The vast rooms of the Castle, its handsome terraces, trim lawns, bowery gardens, and shrubberies of pine and laurel, afforded a delightful sojourn to a dozen or more of visitors, whose wants and requirements made no especial call upon the resources of the establishment. Mr. Crawshay's pineries were famous not only in the county, but throughout Wales; while his preserves—deep shadowed woods with margins of green meadowland, in which silvery rabbits, and long-tailed pheasants gorgeous in brown and gold, were free to roam in the sunshine—were the envy of every sportsman. For the summer visitor there was famous trout fishing in the little Taff that rippled so brightly under the very walls of the castle itself; while farther afield, on the Usk, there was salmon to be killed that enjoyed a repute second to none throughout the country. But surrounded as he was by so many delights and luxuries, it must not be supposed for an instant that Mr. Crawshay was only a fine-weather photographer. True, he spent much money in new lenses, novel apparatus, and studio improvements, but he was one of the hardest workers at the camera. His dark-room was his own proper sanctum, wherein he allowed no one to meddle. His baths, developers, and other agents were prepared by his hands alone, and to his assistants very little indeed was entrusted. Although himself *facile princeps*, he was nevertheless content to receive instruction and advice from others. During the visit of his photographic friends, it was the custom occasionally to institute a field-day, when those who made up the party would, one after another, try their hand at a plate; and it is no exaggeration to say that, although surrounded usually by masters of the art, Mr. Crawshay never failed to reach the common level. Landscape photography he especially loved, since it took him in the open air, and it was no uncommon thing for him to divide a day's excursion between his beloved camera and his salmon rod. In neither occupation was he reminded of his affliction, and hence he thoroughly enjoyed them. No man probably has derived so much gratification and pleasant occupation from photography as Mr. Crawshay, while there are few gentlemen amateurs to whom recent photography owes so much. That he has left his mark upon photographic art no one can gainsay, and there are not a few

among the readers of this journal who will ever retain pleasant reminiscences of Cyfarthfa Castle and the last of the iron kings.

ON THE PREPARATION OF THE PAPERS EMPLOYED IN CARBON PHOTOGRAPHY.

BY ADOLPHE OTT.*

Formerly Chemist in the Establishment of Braun & Co., Dornach, Upper Elsass.

THERE are certainly, however, other descriptions of gelatine which answer the purpose quite as well as those above mentioned. For instance, Dr. Eder† recommends as suitable for photographic purposes a gelatine which, when saturated with water, can be heated up to 30° C. without melting. Again, according to Mr. Cooper,‡ when mixtures of gelatine and chromic salts soon lose their sensitive property, it is due to the former substance having been prepared from bones, and being for that reason choudrinous. In any case of two kinds of gelatines the least soluble is to be preferred, because of the reticulation and graulation which so often—and more especially in warm weather—make their appearance.

For sensitizing, ordinary commercial potassium bichromate can be used with perfect confidence. As regards pigments, only those which are as permanent as possible should be selected. Carmine, for example, which was formerly much employed, must, on account of its liability to fade under the influence of light, be completely rejected. The colouring materials must also possess a certain specific gravity—that is, they must not be too heavy, or they will settle at the bottom of the mixture. Braun and Co. use by preference the following pigments:—Finest lampblack, sienna earth, umber, purpurin, alizarin, and Berlin blue, all ground very fine. We give below some formulæ for papers with a photographic or reddish brown tone:—

A.—Lampblack	6 grammes
Burnt sienna	12 "
Raw sienna	4 "
Purpurin	8 "
Prussian blue	0.5 "
B.—Lampblack	5 "
Burnt sienna	10 "
Alizarin	10 "
Prussian blue	5 "
C.—Lampblack	5 "
Purpurin	10 "
Burnt sienna	15 "
Raw sienna	5 "
Prussian blue	0.5 "

In all the above the weights are calculated to one kilogramme.

The apparatus‡ for coating the paper is not at all complicated. In a vertically placed frame, about 1 metre wide and 2.5 metres high, are fixed, in a horizontal position, two rollers about 15 centim. in diameter, the upper and stronger one being made of polished wood, the lower one of metal. Underneath the latter is a semi-cylindrical trough, which stands over a water bath, and is intended to contain the gelatine mixture. The bath is kept at the proper temperature by passing steam into it. Both the rollers can be raised or lowered to any required extent, and when the apparatus is in use the lower roller is made just to touch the surface of the mixture. The paper, being out to the right size, is passed round the two rollers, and its ends fastened together with gum or paste. In order to keep it stretched a third roller is arranged between the two others on movable arms; this is allowed to rest against

the paper, and keeps it stretched by its weight. When, now, the upper roller is put in motion the paper band will skim the surface of the gelatine solution, and gets coated with an even layer of the latter. It is then cut through, and hung up to dry in a cool place where there is a current of air.

The preparation of the mixture is very simple. Put the gelatine to soak in three-quarters of the above given quantity of water until it is saturated, and dissolve the sugar in the other quarter; then add the glycerine and pigment, and filter repeatedly through linen. Now leave the mixture for some time over the hot-water bath, to allow the bubbles to rise, and filter once more, being careful to prevent the formation of bubbles, and it is ready for use. Of course the temperature must be so regulated that the mixture is neither too thick nor too thin. A strip of paper four metres long and eighty centimetres wide will take up about 300 grammes of gelatine. Paper which is prepared for sale is naturally not sensitized.

Double-tinted Papers.—Suppose we expose a negative—for instance, one of a statue—having a transparent (which is equivalent to a natural dark) background, and underneath it a piece of carbon paper with a couple of coloured films, the upper one of a sepia, the lower one of a purple colour. With a single transfer, the position of the films is inverted, and we have, then, since the action of the light in the background penetrates into the purple tinted layer, the picture of a statue of a light sepia colour on a so-called Pompeian background (sepia and purple give a red which has received this name). A picture of this kind has a very agreeable effect, and similar results may be attained with other combinations of colour. Quite a different matter is it when it is wished to copy a portrait or landscape in two colours. In this case great care must be taken in selecting the colours; it is best to use only such shades of colour as do not differ largely from each other—for instance, dark brown and sepia, purple and violet purple. We have in our possession some priuts (for the most part representing Swiss costumes and landscapes in the Rousseau style) which Herr Braun produced ten years ago on paper of this kind. As the lower gelatinous layer showed a black, and the upper a sepia tint in the shadows, there is observed a remarkable depth, which could not have been realised by the use of a pure sepia coloured tint alone. For mountain and glacier views, also, a paper with more than one coloured layer may be employed with great advantage to reproduce the natural colours—as, for instance, when the lower layer has a dark sepia, the upper one a blue tint, &c.

2. *The Single Transfer Paper.*—This is used for negatives that are drawn off, and which, therefore, reproduce the picture in the correct position, or for copying objects in which it makes no difference whether the sides be reversed. The paper employed is that manufactured by Steinbach and Co. at Malmedy; a single sheet measures forty-five by forty-eight centimetres, and the quire costs 32s. No apparatus is necessary for this kind of paper, as it is merely necessary to pass two sheets, lying the one on the other, through the following mixture:—Dissolve half a kilogramme of Arnette's, or some other kind of perfectly colourless, gelatine in ten litres of water; add thirty-five grammes of chrome alum, and mix this solution, while hot, with one litre of a concentrated solution of white shellac in borax. This mixture is to be used warm, in order that none of the shellac may be precipitated.

3. *The Developing Paper.*—This is used in all cases where an ordinary negative is employed. The picture then appears reversed on the developing paper, and, to be corrected, must be transferred once more. Of this paper two kinds can be obtained commercially: the first is coated with caoutchouc, the second is waxed. A very excellent kind is sold by the Autotype Company, London, under the name of "flexible support," but the author is not acquainted with the method of its preparation.

* Concluded from p. 274.

† PHOTOGRAPHIC NEWS, 1878, p. 173.

‡ A. Martin, *Handbuch der Email-photographie*, p. 247.

§ A description and illustration of this apparatus will be found in the PHOTOGRAPHIC NEWS, 1878, p. 451.

The waxed paper is prepared by passing a sponge dipped in a solution of sbellac wax* over ordinary single transfer paper, and then leaving it to dry. The caoutchouc paper is produced at Dornach, in rolls, by means of the apparatus above described. For this purpose, Malmedy paper of 137 centimetres width is used; a roll of this paper weighs 53 kilogrammes, and costs £14. These rolls are cut into sheets 4 metres long, and either 80 centimetres or 57 centimetres wide, and are coated with a clear solution of 4 kilogrammes caoutchouc and 500 grammes of gum-damar in 75 kilogrammes of pure benzole. One of the larger sheets takes up 319 grammes of the solution, and one of the smaller ones 210 grammes.

4. *The Double Transfer Paper.*—For the preparation of this a cheaper kind of paper, manufactured by Rives, is used; its size is 44 by 56 centimetres, and its price 15s. the ream. It is dipped in the following solution :—

Water	10 litres
Gelatine (Arnette's)...	1 kilogramme
Common alum	300 grammes
Barium sulphate	300 "
Glycerine	50 "

At the time of writing, besides Brann and Co., Monckhoven (of Ghent), Marion and Liebert (of Paris), the Autotype Company (of London), two other smaller French and English firms are manufacturers of carbon papers. As carbon photography is rapidly being extended it is to be hoped that the number of manufacturing houses will also increase.

THE ASPHALTUM PROCESS MADE PRACTICABLE.

BY ADOLPHI OTT.

EVERY photographer who has occupied himself with heliography knows why the asphaltum process, discovered by Nicéphore Niepce, has not found a wider application. It is the low degree of sensibility of the material in question, a degree which requires from one to two hours' exposure in the sun, and even more. Professor Husnik, the learned author of *Die Heliographie* (Vienna, 1878) informs us that the proprietor of perhaps the largest photo-zincographic establishment in the world (Gillot, in Paris) makes use of asphaltum as a photogenic substance, which, he says, he found exceedingly sensible; and Professor Rodrigues, the chief of the photographic section of the kingdom of Portugal, says that he does not expose longer than from fifteen to twenty-five minutes. While Husnik does not give us any idea of Mr. Gillot's secret, Professor Rodrigues asserts that the bitumen he himself employs is very hard, with a high melting point, and almost totally soluble in distilled petroleum, distilling between 80° and 110° C. According to him, the solvent should first be freed from every trace of water by treating it with chloride of calcium; and he gives the following formula for the photogenic layer :—

Common benzine	100 grammes
Lavender oil	3 "
Bitumen of Judææ	8 "

Now we know that there are various kinds of asphaltum of different degrees of photogenic power, as I might call it; the Syriau asphaltum is in this respect one of the most preferable. But even one and the same kind shows sometimes different degrees of sensibility, and most probably Professor Rodrigues had the good luck of having a superior "brand" at his disposal. Quite recently a Swiss photographer, Mr. F. Flanser, in Naefels, Canton Glares, has discovered a method of improving any kind of bitumen by removing from it the

non-photogenic substance. This he does by means of a solvent, which, however, I am at this instant not able to disclose. All that I can say is, that he reduces the time of exposure to fifteen or twenty minutes. The process seems to be perfectly practical, for it is made use of by two large publishing firms, Orell Füssli and Co., in Zürich, and the Brothers Benziger, at Einsiedeln. The results are of an exquisite, I might say microscopic, minuteness, and far outdo the "Abelldruck" (Abel-printing method), a process practised in Cologne, of which you find proofs in Dr. Stein's large work, *Das Licht in Dienste der Wissenschaft*. I enclose you, Mr. Editor, a specimen obtained in this city, and hope soon to be able to forward you a whole collection. Thus far difficulties were experienced in covering large plates, which nearly always are zinc plates; this difficulty has also been overcome. The development is accomplished by means of turpentine. Every experimentalist asserts that by no etching method are so fine results to be obtained, and that no etching process is so easy and quick, as that in which asphaltum is the photogenic substratum, and we therefore can look forward with greater hopes than ever before that the application of this bituminous substance will be greatly increased. Reversed negatives are necessary if the zinc is to be used as printing plate, but if from this latter a print on lithographic stone is required, an ordinary negative will do. I might here recall an observation of Niepce to your mind, that is, if a solution of asphaltum in a half-filled and loosely corked bottle be exposed to sun-light for one hour, or to diffused light to from five to six hours, a higher degree of sensibility is procured. McPberson extracts the resin in question first with ether.

Prof. Rodrigues, in his book, "*La section photographique et artistique de la direction generale des travaux geographiques du Portugal*" (page 54) describes several processes for producing a grain by means of the asphaltum method. One of them consists in covering the photogenic substratum with a very thin alcoholic varnish, and, while yet sticky, by sifting thereon fine plumbago powder, which operation, however, should be done by means of a special contrivance. On slightly beating the zinc, the powder will remain on the varnish. After insolation, the plate is washed with alcohol, which dissolves the covering in removing the plumbago. The grain is formed by a multitude of small holes produced by the opacity of the powder. After this the image is developed as ordinarily.

Probably the treatise of Niépce de St. Victor, "*Traite pratique de la gravure heliographique*" (1856) will now anew be consulted.

Höttingen, near Zurich.

OXYGEN IN THE SUN.*

At the meeting of the Royal Astronomical Society on Friday, the 13th inst., Professor Henry Draper, the distinguished American physicist (son of Professor J. W. Draper, whose work on the "History of Intellectual Development of Europe" has caused many to forget his earlier scientific successes), brought before an audience of English astronomers and physicists the evidence by which he appears to have demonstrated that oxygen exists in the sun. It will be remembered that when, in 1859, Kirchhoff showed how the dark lines of the solar spectrum enable us to analyze the vaporous envelope of the great central luminary of our system, the substances the presence of which was recognized belonged, with one exception, to the family of metallic elements. Iron, zinc, copper, aluminium, sodium, magnesium, cobalt, nickel, calcium, chromium, titanium, and manganese were found to be present in the sun. Besides these metals, hydrogen was recognized. It is doubtful whether even hydrogen ought not to be included among the metallic elements. In that case hydrogen would be regarded as a

* The sweet smelling wax which separates on the surface when shellac is melted in hot water.

* Condensed from the *Times*.

metal which at ordinary temperatures is in the gaseous form, precisely as mercury is at ordinary temperatures a fluid metal. Adopting this, which is probably the correct view, we may say that all the elements the presence of which in the sun had been determined by dark lines—that is, by absent, or rather by relatively feeble tints—in the solar spectrum are metallic. The absence of all evidence respecting some of the other elements might not have seemed remarkable, because it might well be believed that they were present in quantities relatively so small that our means of analyzing the sun failed to detect these substances. But that such elements as oxygen, nitrogen, and carbon, which are such important constituents of our earth, should be absent from the sun, or should not be present in quantities large enough to make their detection easy, seemed surprising. If oxygen were present in very great quantities in the sun, but always lay below the visible solar surface, and was at a higher temperature than that prevailing at the surface, then oxygen might indicate its presence by its bright lines, and could certainly indicate it in no other way. Now, it is evidence of precisely this kind that Professor Draper seems to have obtained respecting this most important element. He had been engaged since 1863 in obtaining simultaneous photographs of parts of the solar spectrum and of corresponding parts of the spectra of hydrogen, nitrogen, and carbon. In examining a series of such photographs, in which the fluted spectrum of nitrogen was in juxtaposition with the solar spectrum, he found reason to suspect that some of the bright lines of nitrogen agreed exactly in position with bright bands in the spectrum of the sun. Pursuing his researches, he found, even at that early stage of his labours, very striking evidence of agreement between the bright lines of oxygen and solar bright bands. It was not, however, till the year 1877 that he was so far satisfied as to announce “the discovery of oxygen in the sun.” The paper thus named was illustrated by enlarged views of the negatives he had obtained. So that, in point of fact, the reader was provided with the very evidence which had satisfied Professor Draper. He did not merely send pictures of what he had seen, but the observations themselves, seeing that the photographs remained precisely as nature had left them, save only for a few reference lines and letters added round the margin to make them intelligible. In these photographs a part of the spectrum of the sun was seen side by side with the bright-line spectrum of air. The bright lines of iron were shown in company with those of air, in order to indicate the exact agreement of the juxtaposed spectra by the coincidence of the iron bright lines with the corresponding solar dark lines. Every one of the oxygen bright lines was seen to coincide with a bright part of the solar spectrum. In some cases the coincidence was very striking, because the bright line of the air spectrum not only agreed exactly in position, but very closely in character also, with a bright band in the solar spectrum. This close resemblance could not in every case be recognized—a circumstance by no means surprising when we remember that if these bright bands in the solar spectrum are really due to the presence of great quantities of oxygen below the visible solar surface, the light of this oxygen can only reach us after passing through the cooler envelope of metallic vapours which produces the dark lines, and must be affected by the absorptive action of those vapours, which, of course, was not the case with the oxygen of the air from which Professor Draper obtained the bright-line comparison spectrum.

Many experienced spectroscopists remained unconvinced by the evidence which Professor Draper thus advanced in 1877. They considered that the dispersive power of his spectroscopic battery was not sufficient to place beyond question the coincidences on which he based his conclusions. Other objections also were advanced which need not here be dwelt upon. In the true scientific spirit, Professor Draper set to work to apply more searching tests to his result. The scale of his enlarged photographs had been half that of Angstrom's well-known normal spectrum. Those which he

exhibited last Friday at the Astronomical Society were on a scale four times greater. The evidence derived from each coincidence was thus increased fourfold in value, the evidence from two coincidences, sixteenfold; from three, sixty-fourfold; and from the eighteen recognized coincidences, about 68,725,000,000 times. He effected also an improvement likely to have great value in other spectroscopic researches. The electric spark through air which gave the air spectrum pursued a zigzag course, like a lightning-flash on a small scale. He wanted a straight flash, or at any rate a flat flash, so that seen from one direction it should appear as a straight line. So he invented what he calls the spark compressor. The terminals between which the spark passes are introduced into a small block of soapstone, and between them a small flat aperture is prepared, between the walls of which the electric flash has to travel. This space is left open on one side, somewhat like the slit of a money-box, and the spark seen from that side necessarily appears as a straight line, though it may have a considerable amount of zigzag play in the plane of the flat space left for its passage. The result of this arrangement is that the spectrum of the air lines (oxygen and nitrogen), as also of the iron lines (obtained by having a little iron at one of the poles), is much better defined and more trustworthy than it had been before this plan was adopted.

TRANSPARENCIES AND LANTERNS.

BY J. TRAILL TAYLOR.*

I ELABORATE, by special request, one or two thoughts thrown out by me in the course of my desultory remarks at the last meeting of the Photographic Section of the American Institute.

Those who were present on that occasion will remember that the expected proceedings—an address on the construction and uses of the magic lantern, by myself, to be followed by an exhibition of photographic transparencies of a somewhat representative type—were nearly made of non-effect by the inadvertence of the committee, who had failed to apprise me, of all others, of the fact that my services were required, until the meeting had been called to order. Under such circumstances, my remarks were of a more discursive nature than would have been the case if I had only had a day's notice of the part that I was expected to play. That any exhibition at all took place was owing to the fact that my lanterns are always kept in a state of readiness, and were in the vicinity of the room in which the meeting was held.

For such purposes as the exhibition of photographic transparencies to a party of from fifty to a hundred individuals, I entertain a strong conviction of the great advantages possessed by an oil lamp over the lime-light. I have tried both sources of illumination frequently, and recommend the oil on account of its greater simplicity, readiness, and the feeling of general comfort it induces. The last of these qualities will be best appreciated by those who have witnessed an oxyhydrogen explosion.

The intensity of the one kind of illumination far exceeds that of the other. But what I here contend for is this: that if the disk be confined to small dimensions, such as six feet, the illumination is quite sufficient to enable photographs to be seen with a due degree of brilliancy, and in every detail. The lantern by which I sought to demonstrate this was of English manufacture, a slight departure from the excellent Marcy sciopticon, which instrument (thanks to Mr. W. B. Woodbury who introduced it into Europe) has entirely revolutionized the lantern manufacture. Marcy's lantern possesses two straight wicks, placed in the direction of the axes of the optical system of the lantern; that used by me has three. The desirableness of getting the cumbrous oxyhydrogen lime-light supplanted

* *Photographic Times.*

by one possessing a greater degree of simplicity is so great that those interested should lose no opportunity of comparing one lamp with another, in order to ascertain which principle of construction is the best, and then to see in what manner that principle can best be given effect to. No photographic society should be without its lantern; and a few minutes of each meeting devoted to the exhibition of such transparencies as the members choose to bring with them, would be both pleasant and profitable. A well-constructed oil lantern (I use *kerosene*) may be always kept in a state of readiness, so that all that is necessary, when its services are required, is to strike a match; and in the course of two minutes the exhibition is being proceeded with.

With regard to the transparencies: if a grey tone be not objected to, they may advantageously be made by means of the camera and wet collodion. A pleasing warm, rich tone may be imparted by bichloride of mercury, followed by sulphide of ammonium very much diluted; but such a method of toning ought never to be had recourse to if the transparencies are intended to be kept for any length of time. I have in my possession pictures toned by mercury, which have faded to such an extent as to render it difficult to discover what the subject is, and this notwithstanding their having been well varnished. Platinum, palladium, or gold form excellent and durable toning agents for transparencies; but the tones are somewhat cold. There is no toning solution extant that can equal uranium, when properly prepared. It imparts a rich, warm bloom to the coldest picture, and, if I am justified in speaking of permanence from a twelve years' standpoint, I can strongly attest the permanence of pictures toned by the salts of this metal; and at the meeting, to which allusion has been made, opinions corroborating my own in this report were freely expressed.

Much as I have worked with bromised collodion emulsion, I have never yet been able to satisfy myself that it produces transparencies of a quality to equal those which may be prepared by other dry methods, *e.g.* the coffee process, and acid (not alkaline) development. An old collodion and acid bath, with copious washing of the plate, followed by immersion in a strong infusion of coffee, provide surfaces that, when dry, will yield magnificent transparencies, provided that an acid pyro. developer be employed. The proportion of silver added to the developer should not exceed one drop of a thirty-grain solution for each picture until the whole of the details are out, when more may be added to impart vigour. The developer contains citric acid in the proportion of two to every three grains of pyrogallie acid. The image should be fixed by cyanide of potassium, and it is advantageous that the old developer, which should have been reserved for the purpose, be reapplied to the plate for a short time. This imparts great richness and warmth to the tones.

There are many occasions when only one transparency is required from a subject; for example, a copy of an engraving to illustrate a lecture. The expense and trouble of taking a negative expressly for this one picture may be saved by making use of a bromised emulsion, such as Newton's, exposing and developing as for a negative, and taking special care to employ alkaline pyro. development. When the whole details are out, let the plates be subjected to the action of dilute nitric acid, by which the silver that forms the opaque parts of the image will be dissolved out. This causes a transformation of the negative into a transparency of singular delicacy and beauty; all that is required to impart vigour to it being a rinsing in water, to remove all the acid, followed by an application (in the light) of the same alkaline pyro. solution by which it was originally developed.

Several of the transparencies exhibited at the meeting of the American Institute by me were prepared in the manner described, which also forms an excellent and sim-

ple method of printing (by superposition) a transparency from a transparency, or a negative from a negative, by one operation.

A LIGHTNING PROCESS.

At a recent meeting of the Chicago Photographic Society details were read by the Secretary of a rapid process, alleged to be the "lightning process." The letter was communicated by a correspondent. The first formula was a Lambert formula.

"Bath, 40 to 45 grains strong; to 4 ounces of solution add half an ounce of a fresh 25-grain solution of cyanide said to be of potassium.

"Collodion.

Ether	2 ounces
Alcohol	1 ounce
Double iodide of cadmium and potassa	6 graius
Iodide of ammonium	4 "
Iodide of cadmium	4 "
Bromide of cadmium	4 "
Gum guaiacum	2 "
Chloride of calcium, C.P.	3 "

"Developer.

Water	16 ounces
Sulphate of copper	1½ ounce
Sugar	1 "
Saturated solution of double sulphate of iron and ammonia	10 to 15 drops
Alcohol	1 ounce
Acetic acid	1 "
Pyrogallie acid solution (5 grains to ounce of water)	½ "

"Continuator.

Pyrogallie acid	10 grains
Bromide of potassa	5 "
Water	1 ounce

"Intensifier.

Water	4 ounces
Tincture of iodine	1 drachm
Alcohol	½ ounce

"A developer giving better details than the Lambert, to be used with ordinary chemicals:—

Water	16 ounces
Sulphate of iron	1 ounce
Epsom salts	1 "
Coffee	½ "
Formic acid	1 drachm
Alcohol	1 ounce
Acetic acid	½ "

Dissolve the iron and other salts in the water, soak the coffee in the solution five minutes, and add the other ingredients.

"Another developer [this is astounding!]:—

Formic acid, ether, and alcohol	½ ounce each
Iodide of ammonium	20 grains
Iodide of cadmium	20 "
Iodide of potassium	15 "
Nitric acid, C.P.	1 ounce
Water	2 ounces

Neutralize with bicarbonate of soda, about a teaspoonful; add until dark precipitate forms; let stand in a warm place over night, and filter.

"This last developer, when rightly made, works quicker than the ordinary, but is apt to work harsh.

"A member remarking on the singular combinations, the Secretary stated that he read them more as a contribution to the curious things in photography, than from any supposed virtue or wonderful properties."

STREAKS IN THE DIRECTION OF THE DIP.

SINCE the approach of the summer season and the occasional warm days which have been experienced, we have received many complaints of streaks in the direction of the dip in negatives. The advent of hot weather commonly brings increased tendency to many photographic troubles, especially in the nature of stains and fog, rendering increased care in all manipulations necessary. The plates should be especially clean, and the fingers should be kept as cool and clean as possible. The bath should be surrounded by a wet cloth. The plate-holders in the dark slide should be kept especially clean. And, in fact, cleanliness and precision should distinguish every operation.

Streaks in the direction of the dip, which constitute the defect under our immediate attention, often proceed from various causes; but there is one common cause, which, judging from recently received complaints, appears to be little understood. Not only from inexperienced photographers, but from old hands, we have received complaints of streaks in the direction of the dip of a foggy nature, the foggy deposit being loose and powdery, and easily removed from the surface of the negative by a touch; but when removed, showing a dark or transparent stain where there had been a light opaque one. One correspondent, who claims ten years' experience, remarks that, whenever he has occasion to replenish his bath, after it has got low by constant working, he is troubled by these streaks, and that although he has tried all he knows, he is not able to prevent this defect, which disappears generally after immersing about a dozen plates in the solution. But he thinks a dozen negatives too many to spoil every time his bath requires replenishing! We think so too! And as the cure is simple and certain, neither he nor others need spoil any more negatives from that cause. If those of our readers so troubled will examine the surface of the solution when the streaks in question appear, they will notice that it is covered with a thin dark, greasy-looking scum, appearing iridescent when examined at different points of sight. This scum, or a portion of it, adheres to the surface of every plate immersed while it is there, and causes the foggy, pulverulent streaks on the surface of the negative. The remedy is very simple: it consists either in preventing the scum from forming on the surface of the solution, or in removing it before immersing a plate. The scum is caused by the dry deposit on the sides of the bath, floating on the surface when the level of the nitrate solution is raised by replenishing from a stock bottle. If, before replenishing, the solution be removed from the bath, which is then washed out and sufficient solution carefully filtered in, no

scum will be found on the surface. When it is found there, however, it is easily removed by drawing a strip of clean blotting-paper over the surface of the solution. The floating scum will adhere to this, and if repeated once or twice it will be entirely removed, and an end made of the streaks.

This is the most common and the most frequently overlooked cause of these streaks. But there are others, not always so easy to trace or to remove. They sometimes arise from the use of a very old solution, and can only be got rid of by trying a fresh solution of nitrate of silver; sometimes from the immersion of the plate too soon, before the bulk of the ether has escaped from the film. A good remedy in many cases consists in keeping the plate in lateral motion from the moment it is immersed in the bath. In some cases we have known it arise from the use of an over-iodized collodion, and its removal was then effected by adding a little plain collodion to the iodized stock in use.

An inexperienced operator recently sent us half-a-dozen plates, each of which had a stain or streak from one corner of the plate. He was much puzzled as to the cause, and was disposed to think some defect in the camera or lens was to be suspected. On enquiry, we found that he never used a plate-holder, but held the plate in his fingers, in all operations, by the corner at which the stain occurred. The stain was simply caused by the free silver on the plate and the developing solution coming into contact with the dirty finger and thumb which held the plate! Such a cause does not often come into operation, we hope, but this illustrated a possibility worth naming, but certainly to be avoided.

FRENCH CORRESPONDENCE.

PHOTOTYPE AT THE MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE—THE PLATINOTYPE PROCESS IN FRANCE—PROFESSOR STEBBING'S GELATINO-BROMIDE—PHOTOGRAPHY BY THE ELECTRIC LIGHT—PHOTOGRAPHY APPLIED TO ARCHEOLOGY—THE AUTHOR OFFERS TO BE OF ANY SERVICE TO THE SUBSCRIBERS OF THE PHOTOGRAPHIC NEWS.

Print Exhibited by the Autotype Company.—The meeting of the Photographic Society of France held on the 6th of June last was far from being so important a one as its predecessor. Probably, however, the readers of the PHOTOGRAPHIC NEWS have already learned what took place on that occasion from the letter of my honourable colleague, who, in alternation with me, fills this space in your weekly issue. However that may be, I cannot but say some words in praise of the beautiful collotype print exhibited at that meeting by Messrs. Sawyer and Co., of London. I have already on a previous occasion expressed my admiration of the splendid works in phototype executed by the Autotype Company; but never before have I seen one of so large a size. Those who, like myself, believe that the whole future of the process of obtaining positive prints from photographic negatives rests with that of phototypy, will join me in congratulating the Autotype Company on the excellent progress which they continue to make in the same path. No doubt the carbon process is highly esteemed, for the services it has rendered are very great; at the same time, its application is limited, on account of its permitting only a small number of copies of the same subject to be taken. On the other hand, the process of phototypy is the one most capable of being worked on a large scale commercially, because of the large number of photographic prints which can be drawn. It is scarcely possible to compare with it the Woodburytype process, by which prints cannot be obtained under similar conditions; besides, the impossibility of using the Woodburytype for direct printing on the paper itself, and with white margins, is one of

the most serious obstacles in the way of working this ingenious process for the illustration of books. Even the mounting of these prints (which is rendered necessary by their constitution) deters editors from employing the Woodburytype process, though it is so obvious and remarkable; they prefer that of phototypie. Some very successful prints, also by this latter process, were shown at the same meeting by M. Frisch, of Berlin.

The Platinotype Process in France.—I can also scarcely pass by in silence, though it may already have been mentioned, the double and doubly interesting exhibition of Professor Stebbing at the same meeting, namely, prints in platinum by the process of Mr. Willis, and some new negatives in gelatino-bromide. This was, undoubtedly, the great feature of the meeting to which I have been alluding. As regards photography in the salts of platinum, M. Stebbing announced that a company for working Mr. Willis's process has been positively constituted in Paris, and he showed a very fine collection of copies printed by this process, which is certainly a permanent one. His communication, difficult as it may be to give credit to the statement, was not received with that attention it most assuredly deserves, for only a minority of the members present appeared to take any interest in it. There were some at the very outset who were not inclined to admit that the permanence of platinotype prints is thoroughly demonstrated; we can only know that for certain, they said, at the end of a hundred years. The want of faith appears to me to be very much like the wish which is father to the thought, considering the actual opportunities offered by science for proving the question. Where such a doubt exists, is it not easy, by a host of well-known devices, to demonstrate the more or less permanent character of the images under consideration? I have myself submitted platinum photographs to the most violent treatment, and have found that they will resist the action of the strongest acids. Now the same can scarcely be said of silver prints on albumenized paper, for even when they are highly intensified with gold, we know they will give way at once under a similar treatment. Besides, the image either is, or is not, formed by reduced platinum incorporated with the substance of the paper. If it be really platinum, why should this body, whose character for permanence is so well established, suddenly become unstable? Can it be objected that its highly subdivided condition has caused it to lose its fixedness? But if this be true, we should soon have a proof of it on submitting these prints to a rapidly and energetically destructive action. Now, as a matter of fact, no change takes place when experiments of this kind have been tried. In my opinion the test of time is not necessary; it is enough to prove that the image is really formed in platinum, and this proof has been established. Another objection to the Willis process caught my ear: *It is so cold!* Now it is quite true that platinum pictures have not that peculiar warmth arising from the bistre or chocolate tinge resulting from the salts of silver; they are rather of a slate-grey colour, and there are cases when a warmer tone would be more effective. But it is a question rather of artistic taste, and very much of custom. When photography was first introduced, what outcries there were against the peculiar colour! Numberless attempts were made even to give silver prints a black or grey colour. But now that a process exists for producing this neutral colour, and one that is well adapted for all kinds of reproductions, one of the first objections raised to it is that which ought to count as one of its principal advantages. If black be so cold, why is it not taken exception to in lithographic and typographic engravings? In some eyes, photographs ought to have a photographic colour, and for this reason the greater number of prints produced by the processes of phototypie or of Woodburytype are executed in *chocolate coloured ink*, so that the public may be satisfied that they are the results of photographic work. But this objection founded on the cold-

ness of platinum photographs is not an important one. There is nothing to prevent the process from being effectively used for the reproduction of objects of archæology, natural history, or palæontology, where the aim is to obtain permanent and faithful copies of such objects, rather than works of art. As regards platinotype portraits and landscapes, they are far from being displeasing; on the contrary, they have an agreeable effect. But we must not wrangle about their peculiar tone, any more than we can dispute about tastes and colours. The whole question has in certain quarters, not without some amusement, been made a question of *climate*. "It is all very well for you English," it is said, "who are already habituated to cold tones; but we Freuchmen, and more especially Frenchmen of the South, must have colours which harmonize with our bright sun and our warm-toned surroundings." Now this is again a kind of inroad into the domain of art: it is like a comparison of the Venetian with the English or Flemish schools. Paul Veronese would have disowned platinum, while Van Dyck would have retained it. But this is not serious; with the affairs of a chemical process, of a mechanical reproduction, of the permanence of results, high art and dilettantism have nothing to do; for them it is a question of individual taste, while we are treating of facts and truths which, having been demonstrated, are the common property of all. The platinum process, it is true, is not likely to supersede phototypie, for its employment is limited to the reproduction of a small number of copies of the same subject. This is also an advantage, because the greater part of his time a photographer is only required to produce a few copies of one subject, and henceforward, when he wishes to give those copies a permanent character, he will have the choice between the carbon and the platinum processes. There is, therefore, plenty of room for employing this beautiful method of photographic printing; it is one, too, which possesses the additional advantage of being four times as rapid as that with the salts of silver.

Professor Stebbing's Gelatino-Bromide.—As regards gelatino-bromide, it would almost have dropped out of notice at the meeting, had it not been for the exhibition by M. Stebbing of some new, nearly instantaneous, negatives, and of the positives taken from them. The expressions of approval with which the members present—and more especially Messrs. Davanne, Bardy, and Ferrier—received M. Stebbing's communications on the value of a sensitive film of gelatino-bromide, are a sure proof that this skilful operator has succeeded in producing plates of constant quality and easy manipulation. In order to avoid subsequent action of the silver on the gelatino-bromide negatives, after they have been exposed to the light, M. Stebbing removes this agent of decomposition during the intensification; and this is how he effects his object:—The negative is immersed in a saturated solution of mercury bichloride, where it remains as long as may be necessary to produce the required degree of intensity; it is then thoroughly washed, and placed in a bath consisting of 200 cub. centimetres of water to which a very small quantity of a dilute solution of pyrogallic acid has been added. To this are then added 2 cub. centimetres of a solution of 20 per cent. of ammonium carbonate and 5 per cent. of potassium bromide. The whole is well shaken, and the plate placed in it, when the negative will be visibly intensified.

Photography by the Electric Light.—Talking of gelatino-bromide calls to mind—why it does so, I will explain directly—the charitable fête arranged at the Opera House by the managers of the *Figaro* for the benefit of the sufferers by the Szegedin inundations. At this fête photography played a prominent part, and contributed not a little to its pecuniary success, thanks to the disinterestedness and the management of M. Pierre Petit, one of the best-known of our Paris photographers. As the fête was held between the hours of nine in the evening and two in the morning,

it is scarcely necessary to say that the photographs were taken by aid of the electric light. One of the proscenium boxes of the opera was fitted up as a boudoir, draped in white and blue, and the strong light produced by the electric current was so diffused over the light and soft colours of this small space as to produce the effect of clear sunlight. Forty-one negatives were here taken one after the other. The precipitation with which work of this kind must be got through, in the midst of such a continually moving crowd as is sure to be met with in a fête, can scarcely be imagined. I have seen the whole of these negatives, and was struck with the comparative beauty and delicacy they exhibit, considering the exceptional circumstances under which they are taken. Sitters succeeded each other almost without interruption, and to the other inconveniences to which the operators were subject was added the public curiosity, which was naturally vividly excited by the novelty of the sight. My own absence from Paris prevented me, I regret to say, from offering any advice on the subject of the arrangement of this photographic department of the fête; if I had had the opportunity, I should have recommended M. Pierre Petit to try gelatino-bromide plates, which would have enabled him to reduce the length of exposure from ten seconds (which was the time he occupied) to less than one second. By this means he could have operated almost instantaneously, and if it be a real *tour de force* to have taken at one evening séance forty-one fine negatives, he could easily have quadrupled that number by the employment of gelatino-bromide. This process is still too new among us for him to have entertained the idea of having recourse to it on this occasion, but it would have been an excellent opportunity of trying it, and if another similar one should arise we must endeavour, if possible, not to let it escape. This experience at the Opera shows once again how numerous and varied are the applications of photography; We have still much to do before this marvellous discovery shall have said its last word, if, indeed, that day should ever arrive.

Photography Applied to Archæology.—The firm of Gauthier-Villars has just published a new photographic work with the principal title, "La Photographie Appliquée à l'Archéologie," and the secondary title, "Reproduction des Monuments, Œuvres d'Art, Mobilier, Inscriptions, Manuscrits." The author is M. Eugene Trutat, Curator of the National History Museum at Toulouse. This highly interesting work is illustrated by some well-executed specimens of phototypie, executed by M. Quinsac, of Toulouse; it is another successful addition to the list of photographic works of whose publication M. Gauthier-Villars seems to have the monopoly. From the same house some new editions will also shortly be issued, and notably that of my own work on phototypie, which is just ready for the press.

Offer of my Own Services.—Several letters which I have received from many parts of England make me think that certain information which I am in a position to give, as well as my own humble advice, may be of use to those of my fellow-workers who read the PHOTOGRAPHIC NEWS. I have no hesitation in stating here publicly that my services are completely at the disposal of such of your readers as may be inclined to avail themselves of them; they will find on my part ready and prompt assistance in all cases where any special information I can give, or where my peculiar relations, can be of any service. I am anxious that the Editor of the PHOTOGRAPHIC NEWS may not only supply his subscribers with accurate and painstaking correspondence, but also that the Correspondent himself should, if I may be pardoned for saying so, be willing and obliging to the extent of his ability.

LEON VIDAL.

FORMULÆ OF PYROXYLINE.

BY DR. GUIDO WOLFRAM.

WE are favoured by Dr. Wolfram with some comments and corrections of the statement of his investigations in nitrate of cellulose, as recorded in *Dingler's Journal*, which appeared in our issue of the 20th ult. He says:—

"As a reader of the PHOTOGRAPHIC NEWS I find in No. 1082, May 30, 1879, a report of my paper upon investigations of pyroxyline, which had appeared in *Dingler's Journal*. I cannot understand where your contributor has found in my paper the statement that there was 'only one real nitro-cellulose, and that should contain 41.89 per cent. NO₂, or nitric oxide,' and if the pyroxyline 'contains less than 41.89 per cent. of NO₂, then the conversion of the cotton is not complete, and there will be found mixed with the gun-cotton a certain proportion of non-nitrated cellulose.'

"On page 8 and 19 of my paper, I say there are four kinds of pyroxyline—

1. C₁₂ H₁₅ (NO₂)₅ O₁₀ penta-nitro-cellulose.
2. C₁₂ H₁₆ (NO₂)₄ O₁₀ tetra-nitro-cellulose.
3. C₁₂ H₁₇ (NO₂)₃ O₁₀ tri-nitro-cellulose.
4. C₁₂ H₁₈ (NO₂)₂ O₁₀ di-nitro-cellulose.

The 1 contains 41.89; the 2, 36.50; the 3, 30.06; the 4, 22.22 per cent. of NO₂. NO₂ does not signify nitric oxide, but *hypo-nitric acid*. N=14, O=16.

"The old formula of cellulose is C₁₂ H₁₀ O₁₀, C=6, H=1, O=8; the new formula, C₆ H₁₀ O₅, C=12, H=1, O=16. After the old formula the gun cotton or tri-nitro-cellulose is C₁₂ H₇ O₁₀ (NO₂)₃; after the new one, C₆ H₇ O₅ (NO₂)₃, and the photographic pyroxyline or di-nitro-cellulose, C₁₂ H₈ O₁₀ (NO₂)₂ and C₆ H₈ O₅ (NO₂)₂. I have not found in the gun-cotton as much hypo-nitric acid as corresponds to the formula of tri-nitro-cellulose, but exactly the half between that and di-nitro-cellulose; therefore I doubled the new formula, and named the insoluble military gun-cotton penta-nitro-cellulose.

"Tetra-nitro-cellulose is the photographic pyroxyline, and wholly soluble in alcohol and ether.

"Tri-nitro-cellulose and di-nitro-cellulose can be produced by treatment of cotton with dilute acids, and only the last, which should not be confounded with the former di-nitro-cellulose, contains often non-nitrated cellulose or unconverted cotton, because it is the lowest form of pyroxyline; but this mass is never soluble in alcohol and ether.

"A soluble pyroxyline, produced with strong acids in a short time (only a few minutes), often contains a small quantity of penta-nitro-cellulose, which is soluble in alcohol and ether, and cannot be separated by any solvent from the tetra-nitro-cellulose.

"Dilute acids and a high temperature give a pyroxyline of pulverulent character, that contains more or less tri-nitro-cellulose.

"I hope, sir, you will find space for this reply in the PHOTOGRAPHIC NEWS.—I am, yours respectfully,

"Dresden, June 6th. "DR. PHIL. GUIDO WOLFRAM."

CHANGING APPARATUS FOR DRY PLATES.

BY MAJOR W. L. NOVERRE.

Now that dry plates are likely to be more than ever popular, if even they do not altogether supersede wet collodion, a consideration of the apparatus available for changing the plates may be of use to some photographers, especially to those in India and the Colonies, who have not access to the shops of our apparatus makers.

Those who have portable dark tents and developing boxes may use them for changing their plates in the field. As the gelatine plate takes so short a time to develop,

some may prefer to develop their plates in the field, and so make sure of obtaining a satisfactory negative; especially will this be an inducement with beginners at the process, who are uncertain about the exposure under varying circumstances, or when the importance of obtaining a perfect negative at once overweighs the trouble and expense of taking the tent and chemicals to the field; for travellers, too, in many cases, both in Europe and abroad, the tent for development on the spot will be useful, because the operation of developing and washing can not always be carried on in a friend's house, or in an hotel.

Additional care in the case of gelatine plates, as compared with collodion, must be taken that all light is excluded, and the window should be provided with one thickness of the best ruby glass, and a second window of the same material should be arranged to slide up when required, so as to have a single thickness for working in a dull light, and two thicknesses when working in sunlight.

A changing apparatus may be dispensed with by carrying the sensitive plates in dark slides, which are constructed for the purpose, to carry two plates, back to back, in each slide; these are perfectly efficient, tolerably portable, and the least troublesome. A double slide is three-quarters of an inch in thickness, so that six slides, which will contain twelve plates, have a thickness of four and a-half inches, being a little more than the thickness of an ordinary one dozen plate box; these slides are, however, expensive, costing thirty shillings each for plates 10 by 8 inches, or £9 for the six slides, and about half that price for plates 7 by 4½ inches. Photographers abroad would have to send the camera or dark slide to the makers to get the double slide made.

The changing bag is a cheap, portable, and efficient contrivance; moreover, it is a thing which a photographer can get made in any part of the world. It consists of a bag made of some material impervious to light, such as black cotton twill, or black and yellow combined; it should fit loosely over the head and shoulders of the operator, and tie with cords round the waist; in front there should be an opening covered with several thicknesses of the most non-actinic fabric procurable, only sufficient light being admitted to see to change the plate. To change the plate, the plate box should be slung by a strap round the neck, so as to hang in a convenient position in front of the operator; the slide may be attached by some simple contrivance to the plate box, or it may be placed in a pocket in the bag made to hold it just below the window. When the plate-box and slide have been adjusted, the bag is drawn over the head and shoulders, and secured round the waist, so that no light shall be admitted; the operator has now both hands free to change the plate.

Another form of changing apparatus is the changing box. The plates are contained in a grooved box resembling the ordinary plate box, but the lid is so arranged that a dark slide (specially made) can be attached to it. By a simple contrivance, the slide containing the plate that is to be changed is brought over an empty groove in the box, and the plate is allowed to slide down into the box. To get a fresh plate into the slide, the latter is brought over a plate in the box, so that the grooves in the box and slide correspond; and by turning the box upside down, the plate slips into its place in the dark slide, which is then removed, and is ready to place in the camera. The price of the apparatus and special slide is about the same as that of six double slides, and it takes up nearly the same space. In any arrangement for sliding the plates from a box into a slide, there is more risk of the plates abrading the grooves, and so producing dust, which is apt to settle on the plates. The efficiency of the above contrivance depends upon all the parts maintaining their accuracy of adjustment; and as the parts are for portability, and are slightly made, it could scarcely be recom-

mended for use in a tropical climate, where all wood is apt to shrink, swell, and twist.

There is another form of changing apparatus in which the plate-box is attached to the back edge of the baseboard of the camera, the lid opening towards the operator; the slide is retained in its place in the camera during the operation of changing a plate. To change a plate, the operator opens up the hinged back of the dark slide, while with the left hand he keeps the plate in its place; the hinged back, being held up by a spring, both hands are free to transfer the plate from the slide to the plate-box. A fresh plate is then placed in the dark slide, the slide and plate-box closed, and the latter taken off the camera. Of course, a cotton covering impervious to light, and leaving openings to introduce the hands, with elastic bands encircling the wrists to keep out the light, must be provided; it should envelop the plate-box and back part of the camera, so as to exclude all light. To enable the operator to see what he is about, an eye-piece can be arranged to look into the apparatus, and a window to provide light; but the plates and slide are so conveniently placed, that after a little practice no difficulty will be experienced in changing the plates.

In conclusion, a few observations on plate-boxes for holding dry plates will not be out of place. Experienced workers prefer wooden to metal boxes, as the plates are liable to be broken in the latter in travelling. Pine is injurious to dry plates; but there is not this objection to walnut wood. The American walnut wood is the variety preferred, as less apt to shrink or twist than the ordinary kinds. The strip of wood which is usually glued inside to the front and back of the box connecting the pieces in which the grooves are cut, and projecting above the edge, should be thicker than usual, so as to admit of their being joined to the grooved pieces by a lap joint, which is less liable to open out and admit light than the simple mitre joint usually employed.

As a further precaution against the entrance of light, a narrow bead of wood may be inserted all round the upper edge of the box, with a corresponding groove round the edge of the lid to receive it. As the hinges, if attached in the ordinary way, would interfere with the grooving and bead, they should be screwed on to the outside of the box. A lock is a useful adjunct to the dry-plate box, as it obviates the danger of any one opening the box inadvertently or through curiosity, and so damaging the sensitive plate.

As the bead must be cut away, thin the lock corners. A brass plate about an inch longer on each side than the lock should be screwed on the outside of the lid, above the lock. The boxes should have two strips of pure (not vulcanized) india-rubber, fixed inside top and bottom, for safety to the plates in travelling. A strap screwed to each side of the box, and united by a buckle above the lid, will be found convenient for raising the box when it has to be moved. The walnut boxes usually sold for dry plates have a sliding lid, and an inner lid with a spring to steady the plates, so that the cover consists of two loose pieces. As the outer lid runs in a groove it is liable to stick in damp weather. These boxes answer well, no doubt, in a temperate climate, but in a tropical climate they could scarcely be relied upon.

PHOTOGRAPHY AT THE ROYAL OBSERVATORY.

In the Annual Report of the Astronomer-Royal of the operations at the Royal Observatory at Greenwich, there are the following remarks on spectroscopic and photographic observations:—

During the past year, spectroscopic observations have been almost entirely suspended, in order that the reductions of accumulated photographic observations might proceed more

rapidly. The sun's chromosphere has been examined on seven days only, and, on five of these, prominences were seen. Two measures of the displacement of the F line in the spectrum of α Virginis, and 26 of the b lines in the spectra of 6 stars (3 of them not previously examined), as compared with the corresponding lines of hydrogen and magnesium, have been made. In five of these, though the stars were of the second magnitude only, a dispersive power equivalent to fifteen prisms of 60° was used. These observations were checked by reference to the F or b lines in the spectrum of the moon or of the sky.

The spectrum of Brorsen's comet has been examined with the half-prism spectroscope, and that of the eclipsed moon on 1878, August 12, with the single-prism spectroscope.

The solar spectrum in the neighbourhood of G has been examined with reference to the existence of bright lines in this region, and several photographs of this part of the spectrum have been taken.

Photographs of the sun have been taken on 150 days, and 228 of these have been selected for preservation. The photographs show a complete absence of spots on 121 days out of 150; and on comparing them with those of the preceding year, when there was an absence of spots on 66 days out of 156, it appears that we have not yet passed the minimum.

On the reduction of spectroscopic and photographic observations it is stated that the spectroscopic observations of all kinds have been completely reduced.

The areas, position-angles, and distances from the sun's centre, of sun-spots and faculae, have been measured in duplicate up to the present time, and the measures completely reduced, so as to exhibit areas in millionths of the sun's visible surface, and heliographic longitudes and latitudes. Great efforts have been made to bring up these reductions, and they have now been perfectly corrected for an instrumental error above mentioned.

On photography as aiding magnetical and meteorological observations we learn that the photographic sheets giving a continuous record of the magnetometers, barometers, thermometers, and electrometers, are in excellent state, the indications of the last-named instrument being specially interesting. The zeros of the photographic curves are determined by readings of the magnetometers and electrometers taken four times a day; and occasional observations of dip, deflexion, and zero of the declination-theodolite give the absolute values of the magnetic elements.

Our former arrangements were adapted only to reductions by monthly means. We are now endeavouring to make them more available for single-day exhibition, in which state the results can be compared more easily with those of other observatories.

A RAPID PROCESS.

BY H. M. BEELES *

I HAVE hesitated somewhat before making up my mind to give formulæ for this process, for so much depends on the manipulation or correctness of method in doing a thing that I suspect some may, after a trial in which directions may not have been very closely followed, pronounce me a fraud and my process a failure; still, in careful hands it will be a success, and will do just all I claim for it.

You will be surprised at the similarity of the formulæ to those so often published, and so I repeat, if you desire to obtain the result, carry out the process in all its details. Two or three dollars judiciously expended will do it. Temperature can be maintained by means of a tin box of the proper capacity to hold bath-holder and developer, a thermometer, and a kerosene lamp.

1st. Plates on which the negatives are taken must be cleaned very thoroughly, if new, with acid, and washed through several changes of clean water with a soft rag, and the last time with a sponge. Be careful each time to touch

* *Practical Photographer.*

all the surface, and remove all impurities.* See that there is no grease or perspiration on your hands. Now albuminize with the following:—Whites of two eggs; two ounces soft water; add twenty drops acetic acid No. 8. Stir thoroughly with a strip of glass, and then let stand until the fibrine separates from the albumen, say ten or fifteen minutes. Filter first through clean muslin, to take out fibrine, then through filter paper or filter cotton which has first been dampened with sulphuric ether, then add sixteen ounces pure soft water. Immediately after washing your glass with the sponge, rinse in pure water under the tap, and flow your plate from a graduate, in the same manner as you would with collodion, and set up to dry in a room free from dust or dampness, *i. e.*, one having a damp atmosphere. Your floor may be sprinkled if necessary.

Collodion.

Alcohol, 95 per cent., or Atwood's	...	1 ounce
Iodide of ammonium (light)	...	5 grains
Iodide of cadmium	...	5 "
Bromide of cadmium	...	6 "
Shake well and add ether	...	1 ounce

Shake well for a few minutes, and filter, then add negative cotton (Anthony's) ... 10 grains

This collodion will keep almost indefinitely, and will ripen in about ten days so as to be ready for use. It will probably be as white as when made, if so, add of any old red collodion, enough to produce a very light sherry colour. If you have no old collodion, add of alcoholic tincture of iodine until the same effect is produced. If all right it will have that bright sparkle which all artists so much like to see. Keep it cool, not cold.

Bath temperature	...	70° Fahr.
Pure soft water...	...	1 ounce
Silver, fused	...	40 grains

Take your silver, if new, and fuse it; and take of any old bath a quantity, and also fuse, and of the two make your new bath, or you may use all old silver; but do not use all new silver, for the old silver is your iodizer, and will cause your new bath to work harmoniously from the first. Acidulate with nitric acid C. P., until your bath works clear; use no more than that. Do not use acetic acid, for there may be nitrite of silver in your bath, and it requires nitric acid to reduce it to nitrate.

Developer.

Temperature	...	70° to 100° Fahr.
Water	...	1 ounce
Photo sulphate of iron from 20 to 60 grains usually	...	30 grains

Acetic acid, No. 8, 1 to 3 ounces to 16 of developer.

If your exposure has been very short, use very strong developer; if you think it fully timed, use developer weak. Of course, strong developer requires more acid than weak does. Fix and re-develop as usual. If this set of formulæ be followed closely with good light and a lens of ordinary rapidity, a fully-timed negative may be made with a 1-2 or 4-4 size lens in from one to ten seconds. If after a time your bath begins to work slow, you will need to fuse it again.

I do not claim instantaneity. It is simply a rapid process.

Do not throw your headrests away; after you have posed a subject they will be very useful in assisting said subject to maintain his or her position, and if you care anything for pose, don't throw them away—don't!

Correspondence.

PHOTOGRAPH OF MIRAGE.

DEAR SIR,—The NEWS for May 30 gives a report from the *Lancet* of the mirage photographed at Tenby. Perhaps

* If your glass has been used before, of course it will be necessary to use potash, soda, or some other method to clean off the old films.

a few words from the photographer in question will not be amiss to explain the reason for taking the tower of Tenby Church.

The weathercock had lost its tail and one wing. A Manchester firm sent men to take it down and repair it. When replacing the cock on the spire on the evening of Monday, 5th of May, I photographed the spire when the two men were at the top fixing it—time as marked by the church clock, quarter to six. One of the men suggested taking another photograph after the top piece was removed with pulley for hoisting the weathercock into its place, to show off the cock to better advantage.

I took another negative—time, twenty minutes past six—when the mirage appeared across the spire, about three parts of the way up the steeple. At first I thought the negative was spoilt—stained; but on examination, when pouring off the developer, I distinctly saw the outline of a boat with flags flying. My first thought was, it must be a wreck with signal flying—this is a mirage of it. Such things had been spoken of in an old "Tenby Guide," which I remembered. It was not until the following week I heard of two gunboats having been launched at Pembroke Dock the same evening, when my attention was drawn to it by the Tenby correspondent of the *South Wales Daily News*. Subsequently several parties who were present at the launch came to look at the photograph, and each one said it was just as the boat lay in the water after the launch, with large flag flying at the stern, and smaller one at the bow.

It was taken on a new glass, that had not been used before, from Claudet and Houghton. Clouds of dust had been blowing over the town during the afternoon. The glass changed several times in the course of the day: towards evening, a peculiar purplish red tinge in the sky, the moon appearing like a ball of deep red fire in the heavens.—I am, sir, respectfully yours,

ROBERT SYMONS.

[In the photograph enclosed the inverted image of the ship is quite visible floating in the clouds behind the spire of the church, and the picture is a very interesting photograph of a mirage.—Ed.]

PORTRAITURE BY GASLIGHT.

DEAR SIR,—In your article upon portraiture by gaslight you very truly observed that the advance of summer quenched much of the interest attached to that subject. Certainly my experiments in that direction might reasonably have ended until the approach of winter, but such was not to be, for no later than last week, two nights, from sunset to near upon midnight, were devoted to some very interesting experiments. They were partly suggested by your remarks upon naphthalizing gas, and partly by the visit of Mr. Sugg to this town to deliver a lecture at the meeting of the British Association of Gas Managers held here last week. Amongst the apparatus shown by Mr. Sugg was a new burner, the largest yet made by that gentleman on his well known Argand principle, which is capable of giving a light equal to 400 candles.

Being desirous of testing its actinism, Mr. Sugg kindly allowed me the use of it, and, after repeated trials, it was found to be equal to that of Wigham's of corresponding intensity. The consumption of gas was about 100 feet per hour. Mr. Sugg is himself an amateur photographer, and is naturally much interested in these experiments—indeed, so much so, that he is constructing a larger lamp, from which he expects to get an illuminating power of 1,000 candles; when finished, Mr. Sugg has promised me a trial of it. Having so far settled the actinic power of the light with ordinary gas, and taken careful note of the exposures, my next step was to try the effect of charging the gas with addition carbon.

For this purpose I was supplied by Mr. Bramley, of this town, with a very compact apparatus which he calls a "carburetor." This was attached to the service-pipe,

and, under precisely the same conditions as before, several negatives were taken, but, to my surprise, with no increase of actinism. The exposure was not reduced one iota by the additional carbon, either with Wigham's or Sugg's burners. This conclusion was not arrived at by an isolated exposure, but by several, and from various sitters. Upon careful comparison by daylight, no appreciable difference could be traced between the negatives taken with and without the "carburetor." With ordinary burners the whiteness and brilliancy of the light is considerably increased after the gas has been charged with extra carbon; it seems, therefore, evident that the burners of Wigham and Sugg are perfect in themselves, and attain without further aid very great actinic power. In these experiments, wet plates were used as being the most reliable, inasmuch as I am more conversant with their preparation, and there could be little if any variation in a dozen or so.

For practice work, however, by gaslight, there is nothing to compete with gelatine plates. I have used those prepared by Mr. Swan with very great success, and in my estimation they are, for gas-light portraiture, the right thing in the right place. They are exquisitely sensitive, and very reliable.

With reflectors there is much to be done. The simple ones I have used have certainly given good results, but with a properly constructed reflector which will utilize every ray of light, it is possible that the burners of 400 candle power will be found amply sufficient for all practical purposes.

In my next experiments, whenever they may take place (certainly not for some time to come), I purpose trying a burner (say) of 200 candle power, or even less, for lighting up the shadow side of the sitter. It may or may not be preferable to reflected light. A trial, however, only can decide that.—I am, yours truly,

P. M. LAWS.

GREEN PAINT FOR STUDIO WINDOWS.

DEAR SIR,—In June 6th issue of the PHOTOGRAPHIC NEWS Mr. J. Traill Taylor gives a long account of a *new colour* for the interior of a studio, with some excellent—and I have not the least doubt, well-founded—remarks concerning it. But I should like to know how it is that blue requires a less exposure; therefore, would not the latter be the best for the interior of studio? I think if there were two studios, one painted a pea green, as Mr. J. T. Taylor suggests, and the other blue, that far quicker portraits could be taken in the latter. Blue requiring a less exposure, a person could be photographed quicker under a blue than green studio.—I remain, yours truly,

Bangor, N. W.

A. CLARKE, Jun.

[Our correspondent should note that Mr. Taylor's paper was a comment upon the proposal of an American photographer, who alleged that he had found great advantage from the use of an olive green for the interior of his studio. We have not tried it, nor seen it tried; but to us it seems to be alike opposed to theory and experience.—Ed.]

Talk in the Studio.

PHOTOGRAPHING THE AMEER.—A correspondent writes to us (*Daily News*) from Gandamak, May 17:—The day before yesterday it had been arranged that after the political sitting was finished, the Ameer was to have another sitting, in order to be photographed by Mr. Bourke, and the special artists of the illustrated papers were also to be allowed the privilege of "gazing on the light of the Ameer's countenance." These proceedings led to a sort of free-and-easy mixing of those present, and the grave Councillors of State threw off the re-

serve of official dignity, and walked about with more freedom from restraint than we had yet seen. The Ameer himself disappeared, and in a very short time returned in a much more gorgeous costume than he has ever turned out in here before. This was perfectly European in all its details. The style was evidently formed after the model of a dress worn by a German, or, most probably, a Russian Kaiser; certainly it was not copied from the Prince of Wales, the Vicory of India, or from any of our officials, civil or military. The coat and trousers were of white cloth, heavily embroidered with gold, epaulettes of gold, and a sash of blue, with three gold stripes through it, was worn over the left shoulder. As no star or other decoration accompanied this part of the uniform, the conclusion is reasonable that it did not belong to any order, but that it was merely worn for the sake of appearance. The head-gear was a steel helmet with gold, and a plume of feathers surmounting it. He was photographed with this helmet on, and then with it off, and this gave us opportunities of seeing more accurately the character of the man's face and head. He parts his hair in the middle, and when the helmet was off, the front view of the face presents a wonderful resemblance to the Duke of Edinburgh; this was noticed by more than one of those present. In profile this likeness could not be seen. The projection of the forehead over the eyes is marked, but the brow retreats very much, the head being remarkably high and small, the height being behind and not in front. The photographic negatives were submitted for his inspection, and then he asked to see the artists' sketches. These rough outlines had only been done while the Ameer was being posed for the photographer, and were made from a distance. They were fragmentary and unfinished, and it was evident the ruler of Cabul did not consider that sufficient justice had been done to his face or his splendid uniform. However, he took everything very good-naturedly, and repeatedly laughed at what was going on. Evidently the cares of State were forgotten for the moment, or the negotiations had gone on favourably during the morning sitting. A group of his Highland Brigade had to be done, and the posing of these uncouth Afghans led to more laughter. An attendant brought the Ameer's chillan, or "huhblo-bubble," which he smoked, and looked on, taking a great interest in all the details of photography, and I was much astonished to find that he could speak English. He cannot be said to be quite *au fait* at that language, still he could form sentences, and managed in rather a slow way to express himself. It would seem that he learned it when a boy, and it is said he can read it very well. Daud Shah took some interest in the posing of the Highlanders; but from the way he pushed the tallest man to the front, and the short ones to the rear, it was evident that a good military appearance influenced his thoughts more than that of picturesque effect. The Mastaufi also took a great interest in the proceedings. He seems a good-natured little man, and smiled and laughed with the others. Indeed they all seemed so happy, one could not for a moment suppose that there was a single hitch in the more serious political deliberations which were for the moment in the background. Being photographed and sketched was evidently quite a new sensation to these people, who have passed their lives in such an out-of-the-way place as Cabul, and they seemed to enjoy the new experiences immensely. Orientals are very anxious about their appearance in a picture. No young lady could be more sensitive on this point, nor harder to please, than they are.

To Correspondents.

R. LAMBERT.—Many of the iodides are sparingly soluble in alcohol, and require some pains to secure perfect solution. It is necessary to proceed as follows:—Place a portion of the salts in a Wedgwood mortar with a little of the alcohol, and triturate them together with the pestle until they are dissolved, adding a little more alcohol from time to time. It is sometimes necessary to add a drop or two of distilled water when the alcohol is very highly rectified, as in your case. That which is now undissolved in your collodion will not dissolve at all without some special aid. Carefully decant off the collodion, and then add a few drops of water to the salts, which, by the aid of stirring and shaking, may produce solution: then add the collodion, and try. But it is a failure difficult to remedy.

NEMO.—The dead black used inside cameras, &c., is lamp-black mixed with size or weak glue. If mixed with a spirit varnish, and applied cold, it will dry dead.

VARNISH.—Splitting of films may be the result of various causes. The character of the collodion is a common cause. The use of an over-acid bath is another cause. The use of dirty or damp plates is a common cause. Under-exposure and over-development form another cause. You do not proceed in the right way in albumenizing the glass, we fear. Beat up the white of one egg with a pint of water, and apply it with a Blanchard brush, which consists of a strip of swansdown calico tied on the end of a strip of glass. When there is a tendency in the films to split a week or two after they are produced, take care to varnish immediately after they are dried, and this will prevent splitting. 2. We do not quite understand the "mottling" to which you refer as appearing after varnishing. We have seen such a result arise from the negative being imperfectly washed after fixing, and leaving some of the fixing salts in the film. The fact that it disappears after a second varnishing suggests that the varnish is somewhat thin, or the plate is suffered to chill before the varnish is dry. 3. The addition of carbonate of ammonia to the fixing bath is an advantage, one ounce to a pint of fixing solution containing four ounces of hyposulphite.

BIG HYPO.—The use of the old hypo bath for toning was discarded because it gave fading prints. The toning such baths effected was chiefly sulphur toning. We cannot enter fully into the philosophy of the subject in this column, but will endeavour to say something about it in our next.

F. A. BATHURST asks for the most perfect process of printing on wood. The question is scarcely sufficiently explicit. Our correspondent does not say for what purpose the printing is required, whether for ornamental purposes, or for the use of the engraver on wood. If he will explain the purpose we can probably help him.

G. C. H.—So far as our knowledge goes, opal pictures are rarely coloured in oil, but in water colours, a matt varnish being used to prepare the surface. If they were coloured in oil, a spirit varnish would answer best, giving the most solid surface upon which to apply oil colours. A good negative varnish would answer, we think.

H. C.—You will find it safer to adhere to the method described by Canon Beechey. Crushing nitrate of silver on writing paper is not so safe as in an agate mortar. The bottle containing the alcohol and silver may be heated in a pan of hot water instead of boiling in a test tube, although the last is simple enough.

HAACKMAN.—The parcel was duly received, and we thought it was acknowledged. We will write in a day or two.

H. B.—The *Moniteur de la Photographie*, published at 13, *Quai Voltaire*, Paris, will best answer your purpose for advertising. We cannot tell you anything of the charges.

C. A. MAXWELL.—We cannot give you a better formula for restoring ferrous oxalate than that given by Mr. Swan on p. 198 of our last volume, in which a hank of iron wire is kept in the solution. It is not necessary to boil them together.

D'ARCY.—Negatives from rapid dry plates are as well suited for enlarging purposes as wet negatives, and, in fact, possess a less granular texture.

DR. LIESEGANG.—Received "Ferrotypie." Thanks.

J. S.—Your letter arrived too late for a full answer this week. See Leader.

L. BERRY.—Thanks. We shall have something to say in our next.

G. NESBITT.—The paper has not reached us.

J. D. HANNAIL.—The authorities at Stationers' Hall do not give receipts or acknowledgments of registration. Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. THE PERMANENCE OF CARBON PRINTS—A NEW APPLICATION OF PHOTOGRAPHY IN JOURNALISM—THE ANNUAL PHOTOGRAPHIC EXHIBITION.

The Permanence of Carbon Prints.—We must once more protest against the absurdity of denying the permanence of pigment prints. That it is possible to produce both pigment tissue and transfer paper of such a nature that the former bleaches, and the latter yellows, need scarcely be said, for there are colours which will always fade, and papers that will always change with age. But if Indian ink, or some other equally good carbon preparation, is the pigment employed, and the paper is a substantial, well-made material, the result will be a tissue that is to all intents and purposes imperishable. But for some reason it has become the custom to cry down carbon prints, not only in this country, but in Germany and France. What carbon photography can do and has done is shown by the magnificent specimens that were produced in the early days by Mr. Swan, and subsequently at Dornach by the great firm of Braun et Cie. To say that these grand specimens of photography fade or discolour would be ridiculous, nor will any pigment prints do so that are prepared under ordinary circumstances. That many tissues have been manufactured of a fleeting character without any carbon in them at all, there is very little doubt, however; but in like manner you may term a thing gold which has no gold whatever in its composition. It is because a good deal of inferior carbon tissue—or spurious, one might really call it—has been manufactured of late that we get these complaints. A photographer seizes a sample of tissue or some delicate purple hue from the first dealer, makes a picture, and puts it into a frame, wherein it is exposed to sunlight for weeks or months. In the end it shows decided evidence of fading, and the experiment is sufficient proof in the photographer's mind that carbon prints fade. The late M. Lacan, our regretted Paris Correspondent, had some misgivings on the subject of carbon prints, from the circumstance that he found in his collection two or three pictures which were certainly very faint impressions. He exhibited them to the Editor of this journal, who recognized them at once as some of the early carbon prints produced at the General Photographie Establishment of the War Department at Woolwich. He advised M. Lacan to communicate on the subject with Mr. Baden Pritchard, under whose care, doubtless, the pictures were produced, and the latter gentleman soon furnished a satisfactory explanation of the fact. They were prints forwarded to M. Lacan for submission to the French Photographic Society in illustration of the continuing action of light rays upon a bichromated gelatine film, and upon the back of the *soi-disant* faded prints were the figures $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{2}$, to intimate that they had been developed immediately after receiving $\frac{1}{4}$ a fraction of their proper exposure, to compare with others that had been kept some hours in the dark before development, and which appeared as if they had been fully printed in the sun. If Mr. Pritchard had not been referred to, these prints might to this day have been taken as undeniable evidence of the fading of really good tissue. Abroad, apparently, there is a good deal of tissue prepared with pigments that fade, for it is not so long ago that M. Reutlinger, the well known Paris portraitist, showed specimens of bleached tissue, and his experience was confirmed by several Berlin photographers. But there was nothing novel in the experience. Everybody knows that there are colours that fade in the sun, and if you make up a tissue with such colours, that, of course, will fade too. We do not wish to deny that there are troubles connected with pigment printing; far from it. And not only this, but we think many err in making far too light of such troubles, and hence it is that they abandon

carbon printing. Such a beautiful process needs no bolstering up from our hands or anybody else's. It is bound to make its way, whether or no; and if there is bad tissue abroad that gives pictures which alter, it is equally certain that the Autotype Company and other large manufacturers are quite capable of supplying a tissue that does not. It is the greater or less difficulties experienced in the printing, and not the non-permanence of the prints, that makes many dislike the process; but they are unwilling to ascribe their abandonment to anything that might cast suspicion upon their own ability. It is a pity this should be so, for since the process has not yet reached the stage of perfection, and you have still to put up with many vagaries in the behaviour of the tissue, sufficient reason in all conscience exists for many to put aside carbon printing for the moment. But until we have proof positive that sunshine really possesses the action of paling lamp-black and stable pigments of a like nature, we shall refuse to believe in the fading of ordinary carbon prints.

A New Application of Photography in Journalism.—An illustrated journal has recently appeared, which owes its origin in the main to photography. It is a publication intended for youth, and called the *Prize Paper*, written and illustrated by juveniles themselves. Prizes are offered for the best contributions, whether in the form of literature or sketches, and these are published. The sketches are all reproduced by photography. A set of rules are drawn up by the Editor to guide the juvenile artists, and these specify, in the first place, that all drawings are to be by pen and ink, or limed in Indian ink with a fine brush. The size of these drawings is also specified, so that reproduction afterwards by means of the camera is a matter of very little difficulty. The sketch is taken away by the photographer, and he returns with an etched counterpart on type metal that can be printed in the printing press. Outline sketches appear best suited for reproduction in this way, and if the lines are clearly traced, and the sketch in the first instance of considerable size, a very neat and pleasing impression is the result. As all the sketches are treated in precisely the same manner, and are, moreover, impartially subjected to a process which works on all alike, photography is made to serve a very useful purpose in the *Prize Paper*, while it certainly is a happy idea to get the readers of a journal to write it for themselves.

The Annual Photographic Exhibition.—The Photographic Society has determined to award medals again at their annual exhibition in October; but the awards are to be made in a somewhat novel fashion. In a word, the judges are to have a number of medals placed at their disposal to award for this or that, as their good sense or idiosyncracies may dictate. The medals are to be given for objects of artistic or scientific worth, which means, of course, that they can just do as they please. We are not sure that the plan is not a very good one; at any rate, it is one worth trying. It is impossible to guess beforehand how many candidates there are likely to be in any one branch, and it is rather a pity, when the show of landscapes or portraits turns out to be an exceptionally good one, that the number of medals available to a class is limited. At the same time, it has happened, and happened frequently, that the award has been a simple walk over, for the simple reason of the paucity of exhibitors. To encourage foreign work, it might, perhaps, be advisable to set apart a certain number of medals for strangers from other lands, for inasmuch as the jury is not an international one, there is always a chance of their claims not being sufficiently understood and recognized. The attraction of foreign exhibitors has, we know, frequently occupied the attention of the Council of the Photographic Society; and it is a well-known fact that unless special inducements are offered, their co-operation, as one can well imagine, is scarcely to be expected. Let us hope that the forthcoming collection at Pall Mall will be a successful one.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY BY THE ELECTRIC LIGHT IN A FRENCH COURT OF JUSTICE.

THE question, whether the Vander Weyde system of the application of the electric light to photography is, or is not, public property, is one which is just now forcibly occupying the attention of the photographic world in France. And there is much reason for this, for the question possesses more than one interesting aspect: there is, in the first place, the point of law as to what rights are attached to a patent taken out in France, and then there is the doubt as to the line of conduct to be pursued by photographers who desire to work the electric light in their own studios.

Naturally there was some excitement at the thought of the advantages which operators by the electric light would be able to possess, once it was completely established, that by a new process really practical results could be obtained. It was remembered that the ill success of the first attempts to introduce the electric light into photographic work had caused them to be quickly abandoned, and that since then they had never been renewed. In the English Department of the late International Exhibition at Paris there were shown some photographs taken by the Vander Weyde system, and professional photographers were astonished, for all the artistic conditions which were formerly wanting were now combined in them. Thanks to the special organs of the press, in which the PHOTOGRAPHIC NEWS was one of the most active in bringing before the public the merit of the invention, it was learned that the technical requirements had been satisfactorily complied with by the new process, and that the employment of the electric light in photographic operations would henceforth be feasible; arguments—or, rather, proofs—not to be foregone were forthcoming. Some time ago, it is true, photographs had been taken by the electric light; the fact that this peculiar manifestation of energy could be successfully substituted for daylight was well known. But the apparatus used only allowed a pencil of rays to be emitted in a confined space, and the result was not what in photographic language is called "clean work." The great problem to be solved was that of the diffusion of the light, and this was successfully accomplished by M. Vander Weyde; according to the *Times* of the 25th of December, 1877, in an article containing an account of this valuable invention, M. Vander Weyde took out his patent in England on the 1st of February of the same year.

In France the discovery was only honoured from afar; people rejoiced at the idea that photographers would henceforward be independent of the changes of light, and would be able to work at any hour and during any kind of weather. There were, indeed, some who, before the Vander Weyde discovery, had rendered the assertion possible—and, indeed, even before electricity had been thought of at all for the purpose—placarded the startling absurdity, *Dull weather is the best*, in large brilliant letters illuminated by gas; but it was merely a means of advertisement, and gave occasion for many a laugh among professional photographers. Business men, whose time, during the hours of sunlight which was propitious to the operator is fully occupied, were prohibited from even going to the photographer, however desirous they might be of having their portraits taken; ladies could not realise their wishes of being represented in evening dress unless they put it on in daylight; actors and actresses, whose costumes are intended to produce any effect by the illumination of the foot-lights only, were compelled, much against the grain, to endure their finery in the full glare of the sun. In France, then, we have been content to stand on our old legs, though we still tried to emulate the photographic feats of the electric light in England.

All the advantages of the process, however, much as the French photographers appreciated them, they could only hope to realize by the employment of an electrical appa-

ratus giving a sufficiently diffused, and at the same time intense, light to produce a photograph. This was well known, and yet the old misleading ways were followed: the meat of the hare was always wanting to make a ragout. At length the patent right for France of the Vander Weyde system was bought by M. Liebert, who, of course, supposed that he had purchased also the right, not only of working the process for his own profit, but also of granting licences to others to do so. He therefore inaugurated sittings for the press, and gave a splendid fête—a description of which has already appeared in the PHOTOGRAPHIC NEWS—in order to give publicity to his new system, which certainly was deserving of all the honour that he showered upon it; in short, he made as much noise as he possibly could, as is the case with every adventurous speculator or fashionable artist. But, on the other hand, M. Pierre Petit has done all this without having purchased anything. At the grand fête held on the 8th June last, at the Paris Opera House, on behalf of the sufferers by the Szegecin inundations, M. Petit exhibited the whole process. It struck him that it would be an excellent occasion for killing several birds with one stone. He would give those who attended the fête the opportunity "*faire sa photographie a la l'electricite*," as says a curious song just now popular at the Alcazar; he would be largely aiding the charity; and he would be advertising the new process so as to benefit himself. But M. Liebert, who had bought the sole right of taking photographs by the Vander Weyde system in France, was not one to allow what he considered an infringement of that right. He therefore applied to the President of the proper tribunal, and, having explained that M. Pierre Petit had not acquired the necessary licence for working with an apparatus for producing the electric light, which was a mere copy of that of M. Vander Weyde, he obtained a legal injunction and the services of an officer to watch and see that nothing was done by night or day in preclusion of the rights of M. Liebert. In consequence, the officer of the court, accompanied by a police officer, and carrying an officially-stamped slip of paper, presented himself at the Opera at the height of the fête. This *coup de theatre* in a place whose frequenters are accustomed to similar *contretemps* did not give rise to so much disturbance as might have been expected. Fortunately for the success of the philanthropic work, for whose benefit the operations had been undertaken, the operations were not interrupted, so that the charity was no loser.

Up to this point, nothing extraordinary had taken place. All that had occurred was in regular order. The owner of a patent had obtained an injunction against a rival whom he had accused of infringing it. This may be seen every day, only, perhaps, not generally at a charitable fête in the Opera House. But the unexpected part of the affair came afterwards: M. Pierre Petit, in reply to his opponent, acknowledges that he operates with an electrical apparatus diffusing light by means of a converging pencil of rays, but he asserts that he has wronged no one, for the system employed by him being public property in France, he had a perfect right to make use of it. For the very reason that he believed himself to have that right, he did not think it necessary to pay for it, as M. Liebert had done. In a word, he laughs at the English patents of M. Vander Weyde.

Now what will Mr. Vander Weyde do in this case? Will he be satisfied to be considered as having invented nothing? Will he submit to the imputation of having illegally accepted payment for licences to work an invention the right to which up to the present no one has dared to deny him—an invention for which he had received the applause of all the world, and the honours and profits for which were thought to be legitimately his due? As may be seen, the question is a complicated and a difficult one. The courts of law are called upon to settle it, and their judgment—which, of course, will cause

all rights legally acquired to be respected—is awaited with impatience.

Faithful to the principles of duty that devolve upon the press, I shall content myself by giving an account of the position of affairs. I shall take care not to assume the attitude of a partisan, and shall leave to a legal tribunal the entire right of pronouncing judgment with a force that cannot fail to make itself felt. In every disputed question, the journalist should not rashly give prominence to his own personal opinions; if he desire to confine himself to the rôle of historian, he must put his predilection entirely on one side. But, if I may be allowed to offer disinterested advice, I would recommend photographers who are anxious to introduce the electric light into their studios without paying for a licence, to wait until this case has been legally and definitely decided. The *Moniteur de la Photographie*, however, seems to a certain extent to approve of M. Pierre Petit's course of action, and to think that there may be some special considerations in its favour; but I fear that this kind of argument may induce some photographers to enter on a path that may prove an insecure one.

In giving an account of the above-mentioned fête in the issue of the *Moniteur de la Photographie* of the 16th of the present month, the Editor asserts that all the instruments used by M. Pierre Petit on that occasion are public property, and not protected by patent. He has taken for his text the protest which M. Liebert has hastened to address to the journal in question, as well as to all the other scientific papers.

But if this assertion be accepted, it is as much as to say that any one can take photographs by the electric light on the new system of diffusion without the least reference to the rights to which Mr. Vander Weyde and M. Liebert lay claim. Now though it is easy to understand the impatience that must be felt by a number of operators to make use of a process by which they are sure to reap a decided advantage, and which will make them independent of their cruel enemy, "bad weather," it would nevertheless be distressing to see an inventor, after having made large sacrifices of time, labour, and money, deprived of the ability of himself reaping some of the benefits and advantages with which he has endowed his contemporaries. Life is a chain of links; the interests of one are bound up with those of another. No one can have the pretension to make his own rights respected without showing that he has the wish to respect the rights of others.

K. VERSNAEYEN.

OUT-DOOR PHOTOGRAPHY.

BY O. W. OSBORNE.*

HAVING experienced considerable trouble and vexation during my first efforts as an outdoor operator, which was caused principally by serving my apprenticeship under the wrong gentleman, who knew very little about landscape work, and having to be my own instructor, I have concluded to offer a suggestion or two for the benefit of the inexperienced, who should choose to lend a listening ear, and thereby remove some of the difficulties which are liable to be experienced by almost every new beginner.

The selection of instruments which are adapted to the work required to be done is of more importance than many are inclined to believe. I would not recommend the selection of lenses of too large an angle, for the reason that unless they are used with skill and judgement the results produced by them will not be so artistic as they would be if a lens of smaller angle had been used, say one of sixty-five or seventy degrees. A Voigtlander Euryscope, or a Dallmeyer Rapid Rectilinear, will be found very useful. They can be stopped down and made to do good work on architectural views. On account of the great power of light they command they will be found especially valuable for out-door groups, and, in

fact, all kinds of quick out-door work. Not only this, but they can be turned to good account under the sky-light, when you will find you have one of the best group instruments made. Of course, it is not to be presumed they will take the place of every other instrument, but for large groups they will do work that no regular portrait lens can possibly do. They will not be so rapid, but what they lack in that respect will be more than compensated for in definitions. There are occasions where lenses of very large angle must of necessity be used, viz., in street and other views in confined situations. It would be folly to pay twice what an instrument is worth during these hard times, for the sake of buying an imported instrument, when lenses are manufactured in this country, at a very moderate price, which combine all the necessary qualities of depth and angle, and are at the same time sold at a fair price. I allude to the Morrison and Zentmeyer wide angle view lenses, which in my opinion are unsurpassed where great depth and wide angle are desired—qualities which render them invaluable where a photographer finds himself crowded into a small street or alley, as is frequently the case in large cities. There are instruments manufactured by other opticians which are as good, but not any better.

In regard to the focal length of lens best suited to size picture to be made, much must, of course, be left to the discretion of the photographer. I would recommend no one to crowd the lens to its fullest capacity, as it would be like putting a steam engine to the test of doing all, and even more than it was intended to do. While the instrument would undoubtedly outlast the engine, the complete ruin of which could be looked for in the immediate future, yet the crowding of a lens to do more than it was intended to do will immediately result in the loss of a first-class reputation to the photographer; for a sorry sort of picture, full of distortions and imperfections, is the inevitable result of such usage. You can illustrate to your own satisfaction what I have said, by trying to make an eight by ten lens picture with a card lens.

In the selection of boxes, tripods, &c., I would recommend that nothing but the best be bought, even if you have to pay a little more for it than you would for the cheap-john stuff that is thrown upon the market to be sold as second-grade goods. A swing back is very essential, and no outfit should be considered complete without one or more boxes of suitable sizes containing the same.

It will be necessary to provide two or more lenses or sets of lenses to accommodate the same size picture; for the reason that, if you are photographing in a hilly or mountainous country, it will often be necessary to photograph a building standing upon an eminence, in which event it would perhaps be necessary to repair to a neighbouring hill, in order to be able to get the horizontal lines of the building to run in the right direction. Now, if you were only provided with one instrument, the chances are about three to one against you; for if of too short a focal length, the image of the building will not be sufficiently large to add the necessary charm which it was intended to add; and if of too long a focus, it will perhaps cause the house to occupy the greatest part of the plate, to the exclusion of other objects which would add materially to the beauty of the picture.

The day is past and gone, and I hope for ever, when a mere diagram of a scene would pass current as a work of art. Now the photographer must possess some artistic skill; he must see that the light falls in the right direction, in order to give the necessary relief, and also that the foreground is not shocked by the introduction of pig-styes and out-houses, which add nothing to, but on the other hand detract from, the beauty of the picture.

A very good way to improve, is to study paintings and engravings of landscapes by eminent artists. Enough real genuine art can be found in half a dozen chromos of different subjects, to make any photographer an artist if he would only silently study them, and try to reason out in his own mind why certain objects are disposed so as to occupy their

* *Practical Photographer.*

respective positions in the picture. A landscape painter would never be guilty of placing a castle or an old mill in the centre of his painting, and choking the foreground with a pile of brush and a lot of old barrels, just simply from choice; for, if such was the case, a spectator would naturally inquire if far more beautiful scenery was not lying behind this pile of débris, basking in the sun's genial rays beneath that beautiful ultramarine sky.

Where a foreground is barren of objects to break the monotony, and the view is one of particular interest, it would be well to introduce a few things, such as rocks, logs of wood, &c., which, if well done, will add a great deal to what would otherwise have been a very ordinary picture. If you can do no more, have your assistant rush out into the foreground, but let him be on the opposite side of the picture from where the principal object is located, for you must remember that all objects introduced as accessories must be in harmony, and also must be unobtrusive.

As I mentioned above, the horizontal lines and also those which are perpendicular play an important part in architectural photography, and upon their direction depends, in a great measure, the success or failure of the photograph as an artistic production. The instrument should be elevated sufficiently to allow the base line of a building to incline moderately upwards. Of course you will observe that the higher you place the instrument, the flatter will become the cornice lines of the building, and the steeper the base lines, and *vice versa*. All lines on a level with the instrument will neither appear to run up or down the paper as they recede toward the horizon of the picture; and therefore, and for that reason, the top or cornice lines of a building should have a *declination* equal to twice or three times the *inclination* of the base lines. When a negative of a building is made with a very wide angle instrument—as, for instance, a 11 by 14 negative with a lens 8 or 9 inches focus—and the building is made to cover almost the entire surface of the plate, the extreme top and bottom lines will appear to approach each other very rapidly; so much so, that a very disagreeable effect is the result, particularly where the instrument was placed too low.

The above is not the only fault caused by placing the instrument too low; for it is immaterial whether the distance increases perpendicularly or horizontally, the result is the same so far as the diminution of objects is concerned. Now do not understand me to say that a building sixty feet high will appear to decrease in size upward in the same ratio as if measured horizontally. Such would be the case if the distance to the top of the building from the instrument increased as rapidly as it does from the instrument to the farthest part of the building, measured horizontally. As an illustration, we will suppose a building one hundred feet square and sixty feet high to be standing on a level plane: now if the instrument be placed on the ground, just one hundred feet away, the farthest visible corner of the building will be almost twice as far away as the front corner, and of course will appear correspondingly smaller.

Now if a negative be made from this standpoint, the top of the picture will appear perceptibly smaller than the base, but the decrease in size would not be so great as the difference between the front and the back corners. The reason of this will appear after a moment's reflection. We have a distance of 100 feet to the building, but it is not, as a matter of course, 100 feet from the instrument to the top thereof; if it was, then objects on the upper portion of the building would appear to decrease in size as much as they would if located 60 feet away on the base-line. The reason that the perpendicular lines do not converge so much as the horizontal ones is because the difference between the base line and hypotenuse is very small—not being more than seventeen and one-third feet, which is only a little more than one-sixth the entire distance from the instrument to the building. Thus it is plain that objects on the top would only appear as much smaller as those at the base, as they would if located seventeen and one-third feet farther

away on the base line. Now if we increase the distance to two hundred feet and elevate the instrument twenty feet, or one-third the height of the building, the decrease of objects toward the top will be very slight; so much so that it would require an accurate measurement to detect the difference.

Another serious fault arises when the instrument is placed too low, and also too close to an object, which is, that the object has the appearance of falling away from the instrument; or, in other words, does not appear to occupy a perpendicular position.

Now do not, in the vain endeavour to avoid one error, run into the opposite extreme, and take your stand too high, and thus produce an effect which is just as disagreeable as the one mentioned above; for if you do, all objects in the picture will appear outlined against the ground, and those which are in the foreground will appear as if falling toward the instrument, and a sort of diagram or map will be the result, instead of an artistic picture.

To those who have no photographs which have been executed by skilled landscape photographers, I would recommend the purchase of a few copies of *Harper's Weekly*, containing the illustrations of English church architecture, for in them may be found many examples which, if well studied, would prove of almost incalculable value to any one having a taste for landscape or architectural photography. Those who have attained eminence as landscape photographers are not in the habit of photographing everything that happens to come before their instruments without first giving the subject some little consideration. It is always best to visit the locality to be photographed a day or two in advance, if not already acquainted with the scenery, and note down the best points from which to photograph the same, and also the best time of day to work from each of the different stand-points, if there are more than one.

Never attempt to photograph any white or light-coloured object with the sun shining full in front, for the result will be nothing but a miserable failure, at least so far as artistic merit is concerned. Better, by far, wait until the sun has passed around to the opposite side far enough to cast a perceptible shadow from every salient point—a shadow as long or broad, or a little longer or broader than the object casting the same is thick or high. As an illustration, a house thirty feet high should cast a shadow about thirty or more feet long.

From sunrise until half-past nine or ten o'clock in the morning, and from three o'clock till as late as you can work, is much better for simple landscapes than if the work had been done in the middle of the day.

NOTES ON STRONG ALKALINE DEVELOPERS.

BY COL. STUART WORTLEY.*

[In the course of a talk with the Editor the other day, he asked me to jot down a few notes for the Journal on the subject of emulsifying bromide of silver.

In 1873 I wrote as to emulsifying bromide of silver in collodion, and never found any difficulty in doing so, provided I mixed them thoroughly in a mortar, adding the one, little by little, to the other. It required knack and somewhat delicate manipulation, but the result was very satisfactory. So with gelatine I act in the same way, and with no drawback; still at present I prefer other methods of preparation.

I believe many negatives are lost from the want of studying the science of development. If room can be found for a reprint of a paper published by me in 1874, it will be found to bear exactly on the work of the present day.]

* The differences to be found in the use of developers of various strengths is a subject to which sufficient prominence has not hitherto been given; and while much has been written on the component parts of an emulsion, but little notice has been taken of the fact that with the same emulsion, or same bath process, an endless variety of negatives or

* *The Photographic Journal*.

transparencies can be produced, and thus to those who use a strong alkaline developer, the following hints will be of use:—

"If your negatives are coming too dense, reduce the amount of pyrogallic acid in your developer; if your plates, on the contrary, are wanting in density, increase the strength of the pyrogallic acid, adding, in the latter case, a drop or two more bromide to control the increased energy of the developer.

"The plate is very nearly as sensitive with a weak solution of pyro as with a strong one, and the development is under great control, as by adding a few drops of pyro from time to time (having commenced with the maximum of strong ammonia), the plate can be worked up to any required density. When liquid ammonia is used in the developer, the pyro and bromide should be applied to the plates before adding the ammonia to the developing solution.

"A modification that I have found of great value during the past summer has been the use of a preparation of gelatine in the alkaline developer. It enables one greatly to reduce the amount of bromide, and indeed, if necessary, to dispense with it altogether, as the gelatine has a great restraining power over the action of the ammonia, and does not, as bromide does, interfere with the production of detail. Gelatine also gives a beautiful deposit on the negative, and anyone having once used gelatine will, I think, adopt it for his future work.

"Tannin and gallic acid can also be used in the developer to replace bromide; but the quality and character of a negative developed with gelatine make me prefer that substance to either of the two last mentioned. You will remember that when gelatine was added to the iron developer some years since, it tended to produce a harder and denser negative than one developed with the ordinary iron developer, and, moreover, the plate required a longer exposure in the camera. The action of gelatine in the alkaline developer is, as nearly as possible, the reverse of all these conditions.

"Another subject which I have worked out is fuming by ammonia as a means of developing dry plates, and with the gelatino-bromide process I find great advantage in its use.

"The less a gelatine film has to do with water the better; and I prefer to develop a gelatino-bromide plate by pouring on it, to commence with, a developer composed of glycerine and water, or gelatine and water, and to which the necessary bromide and pyrogallic acid are added as usual. It is then put into the box and fumed, and a brilliant and perfect image very rapidly appears."

DEFECTS IN ALBUMENIZED PAPER.—WEAK AND STRONG SILVER BATHS.

In his correspondence with our Philadelphia contemporary, Dr. Vogel says:—

"It is a long time since so many complaints have been heard about albumen paper as in the last few weeks, although there was never any scarcity of complaints about this subject. I do not know whether the same cause of complaint exists in America, but I should think that with your variable climate, you would be subject to the same annoyance just as much as we here. The summer is pretty near at hand now, and with the rising of the thermometer an increase of the failures of albumen paper, and a consequent increase of spoiled pictures, will take place. It is a curious fact that the same defect appears often with paper of different manufacturers; and it seems to be a correct deduction from this fact, that one of the causes of the defects has to be looked for in the raw paper, as it is not likely that all the manufacturers work after one method and use the same albumen. Almost all the German manufacturers of albumen paper use Rive's paper, and it is not improbable that the same has undergone some change. One of the main causes of the complaints now heard is the formation of bladders, or blisters, in the albumen paper, and, in my opinion, this can only be caused by insufficient adhesion between the

paper and the layer of albumen, a tendency to blister being thus developed in the albumen paper.

"A proof of the correctness of my opinion is the fact that paper which shows a tendency to blister is ameliorated by laying the same with the back in water till the layer of albumen which lies on top begins to soften. Mr. Wenske first called attention to this fact; and paper treated this way, and dried afterwards, will not show any blisters. The water loosens considerably the structure of the paper, the albumen penetrates deeper, and combines mechanically more freely with the fibre, which prevents, to a great extent, the tendency to blister.

"In proceeding in the above manner, it is necessary to add about one and a half per cent. of chlor. natrium to the water, as otherwise too much salt is drawn from the paper. Many photographers, of course, will find this procedure too tedious, and, in fact, it ought to be attended to by the albumenizers themselves. Whenever I detect any blisters in albumen paper, I apply at once a weak fixing bath, about 1:25. Of course, the pictures must stay half an hour in the bath; but no blisters appear with such weak fixing baths.

"There is another defect in albumen paper much complained about of late, viz., that parts of the pictures are loosened to such an extent in the several baths they go through, that they can be easily wiped off. Sometimes, also, the varnish gets off by itself on those places, and this seems to occur more frequently in the cold than in the warm season; and it is said that by keeping the baths and the wash-water at about 68° Fahr., this annoyance is avoided. Mr. Schaarwächter, here, has noticed the defect, however, also during the warm season, and avoided the same by somewhat longer sensitizing (four to five minutes). Mr. Brandt, here, asserts that the manifold defects in albumen, so much complained about now, and almost unknown formerly, are solely due to the fact that now much weaker positive baths are used than formerly.

"Fifteen years ago, printing baths 1:6 or 1:5 were in general use, but then a number of stock-dealers put albumen paper in the market which, they asserted, needed only a silver bath 1:20; and, in fact, pictures were shown which had been produced with such a weak bath. A great saving of silver was expected; and the weak printing bath paraded in all the leaders of the photographic journals. But it soon became a well-known fact that although a weak silver bath produces good pictures when fresh, the subsequent prints deteriorate very rapidly. In America, this defect was avoided by fuming with ammonia, which way of doing has never been introduced here.

"Even in a strong bath, the sheets which are sensitized first are better than the last ones, but the difference is much less. The strong bath coagulates the layer of albumen better, and allows a more rapid sensibilization; and yet it is found that lately baths 1:10 are generally used, i.e., weaker than formerly, and the cause of it is that the papers are now salted much less than formerly. One to one and a half per cent. of chlor. ammonium are taken now, against double the quantity formerly. The consumption of silver was, in former times, about fifty grammes per sheet, while now it is only twenty-five grammes at the highest; but considering the many defects of albumen lately complained about, it would seem to be advisable to use stronger baths, not under 1:8. Weaker baths require to be controlled, not by the ordinary argentometer, which is always in the wrong with old baths, but in a chemical way, and by intensifying from time with fresh silver salt.

"Those who want to avoid the chemical test will proceed in the following manner:—Note the volume of the freshly-prepared bath, and the number of sheets which have been silvered in it. When the bath has been in use so long that only three-quarters of its original volume remain, add for each sensitized sheet, 1½ gramme (25 grains) nitrate of silver, and dilute the bath till it has reached its original volume again. If the silver bath is always intensified in this way, there will be few, if any, occasions to complain about failures in sensitizing."

THE PHOTOGRAPHIC EXHIBITION.

THE exhibition of the Photographic Society has been now held so many years in unbroken succession, that it may fairly be regarded as an annual institution. In the early days of the Society it was intended that an exhibition should be held annually, and for a few years this intention was carried out. For some reasons, not now worth enquiring into, it was found after a time that the expenses so far exceeded the income that it was desirable to give up a project which, however desirable, was impoverishing the Society. The resumption of these exhibitions under more fortunate conditions we look on as a very happy circumstance, as there is nothing, probably, so much contributes to progressive excellence as the emulation produced by an exhibition, in which, whether prizes are offered or not, a competitive spirit must more or less prevail. Apart even from the competitive spirit, and the aim at excelling which must exist, the annual display of the best work of the best men must inevitably be valuable and stimulative. Such a display furnishes a standard to photographers scattered about the country, who would otherwise be at a loss to know the latest possibilities of the art, what styles are in vogue, and what "fashions" prevail. Such an exhibition also affords the public, interested in photography, to estimate the progress of the art, and to see its highest possibilities, rarely seen in the ordinary commercial practice of photography.

At the next exhibition, to be held for about six weeks during the month of October and the first fortnight of November, the Council has decided that medals for excellence shall be offered as in former years, but with a difference as to the mode of award. A new principle is, in point of fact, to be introduced. Instead of apportioning the medals beforehand to the best works of special kinds, such as portraiture, landscapes, dry plate work, enlargements, &c., as on former occasions, a certain number of medals, or rather an uncertain number, will be placed in the hands of the Judges for award to examples of artistic or scientific excellence. Such an arrangement materially relaxes the conditions under which a jury of artists and scientific men have to study the pictures and make their decisions. To competitors generally the difficulties are somewhat increased, inasmuch as when an aim is made specific, a medal being offered for a defined thing, it is comparatively easy to work to the special end of producing that thing, whether it be portrait or landscape, or what not. Nevertheless, the projected comprehensiveness has many advantages, and offers inducements for originality and novelty of excellence, whilst the old system tended to foster working in grooves. The medals were offered for excellence in known

matters. In future there is no reason why they should not aim at high excellence in beaten paths; but there is also an inducement to originate new forms of excellence in either method or result. The constitution of the jury is well adapted to the rewards of excellence of this kind. It will contain, as on the last two occasions, two painters—probably Royal Academicians—two members of the Council, and two ordinary members of the Society. The painters may be fairly supposed to be most at home in deciding or pointing out the highest pictorial or artistic qualities in a picture, apart from the question as to whether it is portrait or whether it was taken on a dry or wet plate; whilst other members of the jury might indicate especial technical excellence worthy of being distinguished.

Another question may arise which may demand some consideration. If some special novelty or original form of excellence demand an award from the jury, the question may arise as to whether secrecy may be preserved, or whether making a clean breast of the *modus operandi* should be a condition of receiving a medal. To take an illustration. At the last Exhibition, some remarkable pictures were exhibited by a Russian photographer, M. Karelin, possessing special excellence in various forms, but having one feature of an unusually puzzling character. They consisted of groups of figures distributed over planes wide apart, some even sitting outside the window of a room in which the others were seated, all well defied, certainly better defined than, so far as we know, they would be rendered by any known lens. There seemed to be, according to the judgment of experienced photographers, some "dodge" in effecting this. It was, however, a high excellence which a jury endowed with the powers of the next jury might well distinguish by a medal. If so, should an explanation of the method be made a condition of the award? Some will say No: as the method itself might be worth more than a medal. But, on the other hand, it may be answered that the object of a society in offering medals is not to reward an inventor for devising something for his own benefit, but to promote progress, which is distinctly opposed to secrets. We do not undertake to decide the question. We merely suggest that such questions may arise, and should be provided for in the general conditions of competition.

There are now three clear months to prepare for the Exhibition, and we trust that some effort will be made to secure a good one. There is a new motive in the comprehensive openness of the competition sufficient to induce those who have carried off special medals to try in this new wide field.

THEORY AND PRACTICE.

THE recent discussion on gelatine plates at the Photographic Society suggests the idea whether something more could not be done to further our knowledge in this, as well as other matters, by going practically into the subject. The discussion, as the President rightly pointed out, was productive of much good, but a working investigation among expert photographers would do still more. Mr. Browrigg and Mr. Sebastian Davis agreed with each other that gelatine plates, in landscape photography at any rate, showed a lack of appreciation of detail and shadows, while Mr. Werge, on the other hand, no less a practised photographer, intimated considerable surprise at such statements. This is only one point of many that evoked attention in the important discussion, but it is sufficient for our purpose. Why cannot a discussion of this kind be followed up by a practical investigation, a matter in which many gentlemen, both amateur and professional, we feel sure, would be ready to assist. The meetings of the Photographic Society are over for the summer, and summer is of all times the best suited for the practical investigation of photographic problems. In photographic societies abroad it is the custom to nominate "commissions" to enquire into

subjects of a practical nature, the commission usually consisting of half-a-dozen gentlemen who are thoroughly-going photographers, and who are in no way pecuniarily interested in the subject under investigation. Whether it is a new developer, a patent albumenized paper, or a lens of novel construction, this is handed over to the Commission, who practically test the thing to the best of their ability. It might not be convenient to follow in every particular the manners and customs of these Commissions, nor is there any necessity for dubbing the investigators by the high-sounding title of Commissioner; but there cannot be a doubt that we might learn a good deal by following the example of foreign brethren to some extent. Indeed, for that matter, the Photographic Society has on several occasions asked members of its Council to act as investigators, but the occasions have been few and far between. The last, if we remember rightly, was at the time when Mr. Mac-lachlan announced that he had conceived a simple method of preparing and maintaining the silver dipping bath, when the Photographic Society appointed Mr. John Spiller and the late Mr. Le Neve Foster to look into the matter.

But in investigations of the nature to which we refer, there need be no restriction of the number of investigators to two or three. Half-a-dozen gentlemen, or even more, provided they were all of them familiar with camera work, would at a couple of sittings, by the working together and comparing results, bring to light a vast number of facts of practical importance. Take, for instance, the subject of developing and intensifying the gelatine film. So far as the meeting at the Photographic Society expressed itself, there seems at present no perfectly trustworthy plan of intensifying the gelatine image. If suitably exposed and suitably developed, the result was all that could be wished for; but, as Mr. Valentine Blanchard testified, there is a great deal still to be learned before we shall be able to rest on our oars. The experience of many will tally with that of Mr. Blanchard; but it is more than likely that if he witnessed the manipulation of gelatine plates by others who have employed them, he might become cognisant of details he had passed over, just as it is very certain that they, again, would learn something in seeing Mr. Blanchard operate.

The question as to whether gelatine plates really do fail to render half-tone in the shadows is another point that would be soon disposed of in the hands of half-a-dozen practical workers. Many of us unwittingly base our knowledge of a process upon too narrow a foundation. Some have been so fortunate as to obtain a supply of well-prepared and highly sensitive films, while others have been disgusted by a dozen failures. Some have confined their experience of gelatine plates to the studio, and others to landscape photography, and, fallacious as it may be, it certainly seems as if the better reports upon gelatine films come from in-door photographers, and not from those who occupy themselves with landscape work. This, however, would be only one point the more upon which a practical conference would set us right. When we get two such contradictory opinions as those of Mr. Sebastian Davis and Mr. Werge, it is surely high time that some steps should be taken to reconcile them.

But it is not only the gelatine process that seems to invite just now common investigation by practical men. There is the platinotype process, of which we have heard much of late, and about which we shall certainly like to hear more. Again, carbon printing offers many points that might be advantageously taken up. There are, in fact, several subjects of paramount interest at this moment which afford matter for practical investigation and discussion. Are there gentlemen to be found ready and willing to take part in such conferences? We cannot but believe such to be the case, especially among the practised amateurs of the present day. If such gentlemen desired some sanction or appointment, we have no doubt the Photographic Society would readily initiate the good work,

and the present time would be a suitable period of commencement. It is the custom abroad to draw up a report and publish the same in the organ of the Society, and there cannot be a doubt that the Photographic Society would readily take upon itself the expense of printing any such report as might be presented to them. So far as we are concerned, we have contented ourselves with making the suggestion, and those present at the last meeting of the Photographic Society can have no hesitation about the value of conferences or commissions such as we describe. Among amateur clubs there is, we know, nothing novel about the idea of meeting together and working experimentally with a certain collodion, developer, intensifier, &c., and it is the development of this action among photographers of standing which would be productive of so much substantial good, that we desire to see carried out.

DRY GELATINE VERSUS WET COLLODION.

In the above remarks it will be noticed the discussion at the Photographic Society is regarded from an abstract point of view; but we have a word to add of a more essentially personal and practical kind, which is due from us, as we were not able to present at the meeting when Mr. Cowan referred to our opinion of the results of certain negatives produced on gelatine plates. The prints were shown to us without any intimation of any kind as to their respective origin. They appeared at first glance to be both from the same negative, with a difference only in the printing. They were, in fact, cabinet portraits, taken at the same sitting in immediate succession, and precisely alike in arrangement, &c. Both were good, as is all Mr. Cowan's work, but one looked a little over-soft, or, in point of fact, slightly flat; whilst the other, although very soft, full of detail, and fine modelling, was decidedly the more brilliant. We unhesitatingly decided in favour of the latter as the finest picture. We were then informed that it was from a gelatine plate, whilst the other was from a wet plate which had been exposed ten times as long as the gelatine plate. Lack of details in shadows was a complaint made by some of the members in relation to gelatine negatives. Nothing could exceed the perfect modelling, a quality greatly dependant upon detail in the shadows, in the print in question and some others we saw. We have, however, seen frequent examples of the lack of detail mentioned, especially in distant foliage, a grey foggy mass appearing instead of detail. But this we have no hesitation in saying is a common fault of mismanaged alkaline development, and is not by any means a peculiarity of gelatine plates.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.*

THE last meeting of the session was held on the evening of June 10th, at 5, Pall Mall, Mr. J. GLAISHER in the chair.

After the usual preliminary proceedings, the PRESIDENT asked Mr. Valentine Blanchard to favour the meeting with some observations on failures in the production of gelatine negatives, a subject he had kindly undertaken to introduce that evening.

MR. BLANCHARD said: I must begin by making an apology to the meeting. A paper as on other occasions should have been read, but unfortunately it was found that none was forthcoming, and at the last moment it seemed highly probable that there would be nothing to lay before the Society. It appeared to me, however, that it would be a shame if the members were to assemble without having a subject to discuss, and as the question of gelatine plates has of late occupied so much attention—your last three meetings having been largely engrossed by it—I thought that a few remarks concerning the failures I have had in working the process would lead to a profitable discussion, and might

* From the Society's Journal.

possibly elicit some information from members who have had experience in the gelatine process which would be useful to all of us. My attention was directed practically to gelatine plates in November last, when I was unexpectedly called upon to photograph an old lady and gentleman, both over eighty years of age, and from this cause presenting some difficulty to the photographer. The light was not good, but it was a case of necessity, as another opportunity would probably never present itself, and I tried a gelatine plate. My first experiment was a marvellous success and far beyond my anticipations. I have these negatives by me still, and I confess that I frequently look at them with fond longings. Regarding them by my after-experience of the process, I can say that my success was something like that of the beginner in card playing—I was highly favoured by fortune. Never have I in technical excellence surpassed those first two negatives taken in November last, though I have tried many a plate since. After my first success I was so delighted by the shortness of exposure that I was led on to difficulties in this direction, having, I suppose, expected too much of the process. I then adopted rigid precautions so far as exposure was concerned, and I must say that some of the results have been perfectly satisfactory—more satisfactory, indeed, than I anticipated. I found that hurrying the development was a fatal error, so I waited patiently, using a minimised quantity of pyrogallic acid and ammonia, and generally to my satisfaction reaped the reward of my patience. The possibility, however, of doing so much by patient development tends to induce one to shorten the exposure in the hope of afterwards compensating the loss; development is prolonged, and then comes the well-known yellow deposit. This was my experience, and I found that the prolonged treatment of the gelatine with ammonia inevitably produced this yellowness. Some of the negatives I obtained were to all appearance, technically speaking, I thought—judging by a long familiarity with wet plates—absolutely perfect, and delighted me beyond measure. But when they came to be printed I was woefully disappointed, for owing to their peculiar colour they were of such a density that it was only with difficulty the prints were obtained from them, and even then were much harder than from the look of the negatives I should have been prepared to expect. I then went to the opposite extreme. I gave the full exposure, and by using less ammonia and shortening the development obtained negatives just as thin as the others with the short exposure and prolonged development were too dense. Then came the question, how to intensify these thin negatives and get them to print. I tried various methods of intensification with more or less success. Among others I tried pyrogallic acid and silver, and iron and silver; and though I had no difficulty in getting intensification with the latter, I was met with a new difficulty, for the deposit was uniform all over the plate, upon the halftones as well as upon the high lights, and the remedy was worse than the disease, for the intensified negatives took ten times longer to print than those which had had the prolonged development. Intensification of this kind was certainly no advantage, and it then became a question as to whether the yellow deposit could be easily and safely cleared from the negatives, and what method was best to use. I found on the whole that the best medium for performing this office was hydrochloric acid, and that it could be so used as to still preserve a certain amount of control over the result. But with the hydrochloric acid came another serious defect. The film of gelatine, which under the tedious process of development showed no signs of "frilling," became loose and detached from the glass directly the hydrochloric acid touched it, and of course the picture was at once rendered worthless. A remedy for this defect, I found, however, consisted in drying the film before the hydrochloric acid was applied, and negatives treated in this way showed no tendency to "frill." I am inclined to think that many of my failures with the gelatine process have been caused by my practice—which in my work with wet plates I have always considered a *sine qua non*—of using the full aperture of the lens. One of my "crazes" is, that a lens which will not bear every kind of fixed stop being punched out of the tube, and being used quite free and unobstructed, is worthless for my purpose. Of course I use stops, but I prefer to have absolute control over them, and hence, as I say, I must be able to use the lens with its full aperture. But even with a blackened tube there is a possibility of reflections backwards and forwards, and in the use of such a tube with gelatine plates these reflections may very likely have been at the bottom of many of my failures.

With a good many of my first results I got a number of spots or bubbles on the negative which troubled me considerably until a cure was suggested by Mr. Werge. I must confess that my first experience of Mr. Werge's method rather terrified me, for seizing the plate he polished it with such vigour that I had dreams of the possibility of a skating rink being constructed of a vast gelatine negative, so hard and so polished had the surface become. I have, I think, gone over all the sources of trouble which at this moment I can recollect, and I hope that some other member will supplement the few remarks I have been able to make. I might say, in conclusion, that with regard to the use of hydrochloric acid, Mr. Cowan in all probability will be able to offer some valuable suggestions.

MR. COWAN, on exhibiting some negatives for inspection, said: In showing the negatives which I have submitted to-night, I had no idea of saying anything on the subject of the gelatine process. I might, however, after hearing Mr. Blanchard's remarks, say one or two things which occurred to me while he was speaking. With regard to the use of hydrochloric acid in removing the yellow colour, I should certainly say, that if anyone uses a strong solution while the plate is wet, he will be almost certain to have "frilling." But if the plate, after being fixed, or after having been dried, be thoroughly soaked in a solution of alum, not the slightest effect will be produced by the hydrochloric acid. I have used it as strong as 50 per cent. My practice is, as soon as the plate is developed, to put it into a solution of alum, and allow it to remain there two or three minutes at least. It may then be fixed, but after fixing, again placed in the alum solution, and let remain there a considerable time—even half an hour. If this method be adopted there need not be any anxiety about frilling; indeed, the film, when dry, will be so hard as to bear very rough usage, and in many cases varnish may be dispensed with. I am inclined to think that the process of development may be simplified, and the working conducted with greater ease, by using a diluted instead of a concentrated solution of ammonia and bromide; and in practice I find it better to substitute for the old plan the making of three separate solutions. Thus starting with one solution of the ordinary proportion of bromide and ammonia to the ounce of water, have a second containing half as much again, and a third double as much to the same amount of water in each case. By using equal proportions of either of these solutions, and a double strength solution of pyro, the development is kept more perfectly under control. I do not find there is the least difficulty in reducing the density of a negative. Say that you have one that looks yellow: all that is necessary is to wash it in alum, and take it down with hydrochloric acid; but with respect to intensification, the matter is not so simple. I must confess that, personally, I have little faith in any of the methods yet known; at the same time, I remember taking a negative which was extremely thin, and asking a friend to intensify it, and in this case the intensification was perfectly satisfactory. I think that in any case of intensifying with silver, the shadows should be cleared with iodine, and then exposed to light.

MR. PAYNE JENNINGS. I have had some experience with gelatine plates, and I think I may say I have met with exactly the same difficulties as those which Mr. Blanchard has mentioned. Certainly, I have met with the difficulties of intensifying and of frilling when treating a negative with hydrochloric acid to reduce intensity. I quite agree with him as to the necessity of drying the plate before placing it in the hydrochloric acid, and that under these circumstances frilling does not occur; and I also agree with Mr. Cowan, that a preventive is found in the use of alum. I question very much, however, whether hydrochloric acid is the proper agent to use under such circumstances. I am disposed to believe that, in reducing intensity, hydrochloric acid, in addition to attacking the high lights, also affects the shadows, and that we are still in want of a suitable agent for the reduction of overintense gelatine negatives. With reference to intensification, I am afraid that all present methods are uncertain. Sometimes it will happen that a negative is procured of a good intensity, but not what one would term the proper intensity, and the use of an intensifier does not act upon the plate in the way we would wish it to do. There can be no doubt that what we want in gelatine work is a reliable method of intensification, and also a good method of reduction of intensity. I have used for the latter purpose a solution of perchloride of iron, but there is the rather strong objection that it turns the film of a yellow colour throughout. At the same time, in some cases it reduces admirably, but the

colour is most difficult to judge, and very apt, without a very large experience indeed, to lead one astray. It has certainly one advantage over hydrochloric acid; it does not attack the shadows, but confines itself to the high lights; but, as I said, its colour is so yellow and peculiar that it must almost be pronounced to be unreliable. I question whether, after all, it is possible to get results from the gelatine process quite equal to those obtained from the wet. It has, I admit, a great advantage in its portability, and, of course, everyone should give it the fairest trial; but my experience is that it does not give such fine results as are possible with the wet. At the same time, I am not going to give it up, and am shortly going to test it with some large plates. Every photographer is, I think, in duty bound to try it to the best of his ability, and in every manner possible; but I cannot help feeling there is something in connection with the appearance of the finished print,—whether it be an advantage or disadvantage, I am not at present prepared to say,—a certain want of brilliancy, which is not apparent in the print from the wet plate negative, and I think that fooling of pleasure which one has in looking upon these dry-plate negatives is one that is deceiving, and will tell against them when the feeling wears away. My great hope is that, in spite of the present superior sensitiveness of the gelatine process, we may yet see collodion as sensitive, or more so. I would certainly prefer collodion to gelatine, if it could equal it in rapidity. However, I am about to take out some more plates, and may be able to speak better of it when I return. I shall certainly not give it up just yet. As I have already said, what I should like to see is a method of intensifying and also of reducing the intensity of gelatine negatives in a certain and satisfactory manner.

The PRESIDENT. Has your experience, Mr. Jennings, extended to portraiture, or has it been confined to landscape?

Mr. JENNINGS. To landscape entirely.

The PRESIDENT. It is necessary to state this, as I believe the conditions differ considerably.

Mr. JENNINGS. Yes, there is a good deal of difference in working those plates in the studio and out of doors. For portraiture, I have no doubt they are in some respects superior to collodion; but in landscape, they appear to lack something which wet plates possess.

Mr. BROWNIGG. I have tried the gelatine plates against collodion, both being under exactly the same circumstances, and I must endorse Mr. Jennings' opinion that I could not get such favourable results with the former as with the latter. With all the trouble and inconvenience of the wet process, I yet prefer it to the gelatine. What struck me as a peculiar feature in the gelatine process is, that in the deep shadows you cannot produce that cleanness and detail that you can get in a wet plate, the exposure being given which the well-lighted parts of the subject required, and beyond which they suffered. In photographing a landscape, for instance, the dark shadows under trees are devoid of detail, and these dark portions do not appear to affect the plate in the same proportion as the high lights. In a landscape lighted by sunshine, where the high lights are very marked, this difference of sensitiveness is very apparent, and while the lighted portions may lose all force from over-action of light, the parts in shadow may be under-exposed. I tried three 12 by 10 plates under different conditions, the result bearing out this statement. No. 1, an oak in full leaf, ninety seconds' exposure: all the parts in good light were fully exposed, but there was almost no detail in the shadows. No. 2, a dark subject in a wood, ten minutes' exposure: good detail in the shadows, but the negative was worthless from over-exposure in the high lights. No. 3, another dark subject, ten minutes' exposure. In this view there were no strong lights, the result being a good negative, with the proper amount of detail in all parts. In the wet process, the development can be so humoured as to compensate this difference, and we all know what an iron developer is capable of in this direction. But in working the gelatine process, this power of modification cannot be used, and the picture suffers accordingly. It also seems to me that, in many of the photographs produced by the gelatine process, there is a great want of sharpness. I am not sufficiently versed in the mysteries of photographic science to be able to assign a cause, but I might suggest that the sensitiveness of the plates to a vivid image would, from the high light being destroyed, be liable to produce a want of sharpness. In albumen plates, for instance, when the exposure is long and the action slow, the sharpness is wonderful. This, of

course, may not be the proper solution of the phenomena, but I am certainly confident that it exists, and is especially noticeable in the case of a bright light.

The PRESIDENT. You also have confined yourself to landscape photography, Mr. Brownrigg, in connection with gelatine plates?

Mr. BROWNIGG. Yes.

Mr. SEBASTIAN DAVIS. The effects described by Mr. Brownrigg are similar to what I have myself seen. With reference to the adaptability of the gelatine process to portraiture in preference to landscape work, I believe the over-sensitiveness of these plates to the high light is not so detrimental in the former as in the latter. In photographing a landscape, you have a number of deep shadows which you cannot illuminate; but in portraiture, on the contrary, you are able to modify your lighting in such a manner that this strong contrast is avoided. It is well known that the skill of the portrait photographer is shown in his management and mastery of the lighting. I am strongly of opinion, not only with regard to the dry, but with reference to the wet, that no process is quite satisfactory for landscape purposes unless you can develop all the details, and afterwards, if, and as, necessary, intensify. In going round the last Exhibition, and looking at the pictures stated to be from gelatine plates, I remember it was said, "These cannot be gelatine, because of the details in the shadows."

Mr. WERGE. I am rather surprised at the observations which have been made by some of the gentlemen, and especially at the remarks which have fallen from Captain Brownrigg and Mr. Davis. These gentlemen have stated that there is a want of definition in the shadows of the plates prepared by the gelatine process. I must say that, so far as my experience has gone, quite the contrary has been the case. If there is anything which gelatine does, it certainly renders detail in the shadows. Of course, if you do not expose sufficiently you will get want of detail, but then the remedy is easy enough. I may remark, with regard to portraiture, that if the right exposure be given, there will be more detail in the shadows given by the gelatine process than by any other. Mr. Blanchard has already told you how to get rid of the bubbles—the soap-like bubbles—caused by the ammonia during the process of development. The removal of these bubbles by the hand is of course effectual, but the cleanest and neatest way, I think, is by means of a broad camel's hair brush, which answers admirably for the purpose. The camel's hair brush has also another advantage: it can be used to lead the developer over the film, and thus enable one to locally treat the negative, and in some measure to modify the development, a possibility which has not previously been claimed for the gelatine process. With regard to "frilling," it can certainly be obviated by the use of an alum solution, but the solution must be strong enough, and the plates immersed in it long enough. To be on the safe side, I think it is very important to apply the alum to every plate, because you never know how the plates are going to behave. Of course, there are instances in which plates have been treated with hydrochloric acid, and have not shown signs of "frilling;" but it is very uncertain; while, on the other hand, if you invariably use the alum solution, you may immerse them in the hydrochloric acid to clear them as long as you like. I find that a few drops of the acid—say a drachm to half a pint of water—makes a solution quite strong enough to clear off the yellow stain. If this proportion be observed, I do not think it is likely that the half tones will be interfered with; at least, I have never observed it do so. With regard to developers, I may say I have used pyrogallic developers extensively, but on the whole I have a preference for a developer of ferrous oxalate. One of the drawbacks in the use of the latter is the slowness with which the plates develop; the exposure, however, is very uniform. For transparencies the ferrous-oxalate is also decidedly the best. The transparency I have brought with me to-night was made on a gelatine plate; exposed to the light of a jet of gas for fifteen seconds, and then developed by the ferrous-oxalate, the development occupying about four minutes, which on the whole is rather quick. The oxalate developer used was at least three weeks old, and had been used every day; indeed, I find this developer can be kept for two or three weeks without showing any sign of decreased power or slow working. It may be said to be as good as on the first day it was made. It is also an immense advantage in using the ferrous-oxalate that the bubbles, so frequent when a pyrogallic developer is used, are entirely avoided. The plates seldom need to be

treated with the alum solution, for there is no occasion to resort to hydrochloric acid. There are no yellow stains, and the appearance of the negative in colour is more like that of a wet plate. Indeed, the colour of the negative developed by ferrous-oxalate is all that can be desired. When a pyro-developer is employed it should be modified to suit the subject and time of exposure. When brilliancy is required, increase the strength of the pyro, and when softness and abundance of detail are wanted, diminish the quantity of pyro and increase the proportion of ammonia. Halation is observable on *thinly coated* gelatine plates only. If the gelatine films have the requisite opacity, there will be no signs of halation, but even this defect is rendered more visible by the use of a pyro-developer than by using a developer of ferrous-oxalate. The other day I gave two exposures on a thinly coated gelatine plate, cut it in two, and developed one half with pyro and the other with oxalate. The pyro-developed picture exhibited the appearance of halation in a much more marked degree than the oxalate-developed picture, though the time of exposure was the same on each portion of the plate. When thinly-coated gelatine plates are employed, they should be "blacked," especially for landscape work; but the simplest method is to select those plates that possess the requisite opacity without backing.

Mr. PAYNE JENNINGS. I think gelatine workers generally will not find any lack of half tone or detail, if proper care be taken to give the right exposure. The great fault in landscape work is, as I have said before, a certain want of brilliancy or sparkle in the high lights.

Mr. DAVIS. I think there is a little misunderstanding on the question of sufficient exposure in reference to what I said. Without a doubt, a full period of exposure gives all the detail in the shadows; but it is, I think, at the expense of brilliancy in the high lights.

Mr. COWAN. I have several times noticed that though many people use the same developer, they do not appear to get the same results. An experiment of this kind may be very easily tried. For instance, take a gelatine plate and expose it, and then cut it in half. Develop one half with a developer containing the full amount of ammonia; and then take the other, and develop with the same strength pyro, and the same amount of ammonia and bromide, but adding only a small proportion of it, until the high lights show well, and then gradually adding the remainder. The difference in these two plates will be, that while in the one you get flatness, in the other you will have brilliancy.

Mr. PAYNE JENNINGS. I should like to ask Mr. Cowan one question. We are, of course, all agreed as to the superior rapidity of the gelatine plates over the collodion ones; but I should like to know from Mr. Cowan whether he considers the best results obtained from gelatine are equal to the best results obtained from collodion?

Mr. COWAN. The best answer I can give to that question is this:—Some time ago two prints were shown to a member of the Council of the Photographic Society, and he was asked to decide which was the best. He did not know how they were done, nor whether they were from wet or dry plates. "There is no difference," he said, at first: "they are from the same negative." But after examination, he at last gave the verdict in the favour of the one which happened to be from a dry plate gelatine negative. The prints were also soon after shown to Mr. Wharton Simpson, and he, without knowing anything of the negatives, also decided in preference of the gelatine plate. The pictures, I may say, were portraits; the dry plate exposed one-tenth the time of the wet. The complaint of many is that the gelatine plates lack brilliancy, but I think it will be found that the method of using double strength solution of pyro, and gradually diluting it down with equal proportions of the ammonia and bromide solution, certainly favours brilliancy, and that the use of a weak solution of pyro, and the addition of the full amount of ammonia and bromide, at once tends to give flatness.

Mr. HERBERT BERKELEY. I am inclined to believe that the want of sharpness in the gelatine plates complained of by some gentlemen, is caused by halation and by the extreme sensitiveness of the gelatine film. As regards the absence of "frilling" in those plates which had been dried, I have found plates which have been developed become, after a time, even insoluble in hot water. I have by me some gelatine plates

which were prepared some three years ago, and were merely kept for experimental plates. The other day I was induced to clean off the films, using a solution of carbonate of potash for the purpose. The films lastly left the plates in a tough condition, not unlike collodion; but on holding the films over a gas-flame, they were found merely to break up, and not to dissolve. Plates which have been kept long, but not developed, also lose much in solubility. Plates well kept, I have found, are not so liable to blister as those newly prepared.

Mr. BOLAS. When gelatine is kept for a long time in a dry state there appears to be a tendency for it to become harder or less soluble in water. In the case of pure gelatine this action is extremely slow, a number of years being required for any noteworthy effect to be produced, but the presence of certain pigments increases its tendency to harden, and it is probable that silver bromide has a like influence. Gelatine preserved in a moist state often undergoes a reverse change, becoming more soluble, gummy, and soft.

Mr. WERGE. I have lately had a curious experience with a number of gelatine plates, which had been put away damp and had become mildewed. The plates were covered with a multitude of small spots, and were apparently spoilt. However, I thought I would see what could be done, and I washed the plates in clean water, of course in the dark room, and found that the spots disappeared. When the plates were exposed and developed, I found they produced as perfect pictures as any I have ever tried. There is no necessity to throw plates, which have been thus kept, away; they only have to be washed and again dried, and they will keep and can be used as well as those newly prepared. I have observed, also, that these spotted plates can be developed perfectly in the ferrous oxalate solution without previous washing. If, however, the pyro-developer is to be employed, such plates must be washed previously, and may be exposed in the camera at once in the wet state, or dried and used under dry-plate conditions.

Colonel STUART WORTLEY. One of the peculiarities of the gelatine plates observable in practice is that they will frequently frill in certain parts of the process. If, however, the plates are immersed in an alum solution, taken out and thoroughly dried, almost anything can be done with them. There is something very peculiar in the gelatine plate if it has been thoroughly and completely desiccated, as after having been so treated you can moisten it again and carry on any other operation without fear—so much so, that if I get any yellow stain, it is only necessary to harden the gelatine film either by alum or alcohol, and then to remove the yellow stain by hot water. It should be borne in mind that there are a great many different kinds of gelatine plates in the market, and the treatment which will do for one kind of plate will not do for another. As a natural consequence, the experience of the photographer is dependent upon the kind of plate he has worked with. It is, therefore, not at all impossible that Mr. Brownrigg has been using a plate very different from that used by Mr. Blanchard. While this wide difference exists, it is evident that unless we can lay down some kind of standard as to what the gelatine process really is, we shall be giving advice to our friends totally unsuitable to the plates they have been accustomed to, and which may want another kind of treatment altogether. Some plates, for instance, are much more desiccated when sent out than others. There is one kind of plate which is very liable to the yellow stain, and another kind which is exceedingly free from it. It is plain, therefore, that each must have its own treatment. I have not been able to trace the yellow stain to its foundation, but I may say that I disagree with the principle of a developer without bromide. I have always found in bromide a great preventive of the yellow stain. In 1874 I published a formula in which I recommended the addition of gallic acid to the pyro developer. Gallic acid appears to have the same restraining effect on the gelatine plate as bromide, and does not at all favour the yellow stain. I do not know in what way it restrains the pyro, but that it does so there can be no question. The strength of gallic acid I used was 48 grains to the ounce, and added from 10 to 30 minims thereof per ounce. I have thought for a long time, with regard to this subject, that photographers do not pay a sufficient attention to the possible variations of the developer. A few days ago, Mr. Russell Mannors Gordon came to me, and I showed him a large series of gelatine negatives of a great variety of subjects. He said to me, "I do not suppose you used the same developer to the whole of these?" "No," I replied; and, as a matter of fact, I almost always use a different developer, ranging from 1 minim

of pyro solution up to 25 minims, so that I can use that which is suitable to the character of the negative. This point I do not think is sufficiently attended to. A certain formula is adhered to, the developer is invariably made of the same strength, and, whether the subject is well lighted or whether it is full of deep shadows, the treatment is the same. This habit, possibly, we have got into from our constant use of the wet process; but nobody who recognises what I have written for many years can fail to appreciate the extraordinary effect of a varying proportion of pyro on the resulting negative. I would undertake to take four subjects, each of a totally different character, on one large gelatine plate, and by varying the strength of the pyro developer, get equally good results in each case. If by using a weak developer it makes the development any longer, I do not see any disadvantage, because it makes the whole process more manageable, and enables you to get a better class of negative. With regard to intensification, I would say that if anyone wishes to intensify with pyro and silver, it is only necessary to add a minim or so of nitric acid, and the development may be proceeded with straight ahead without fear of any fogging in the shadows. Iodine used previously will answer the same purpose, but either that or nitric acid should always be used. Gelatine plates should also be washed far more thoroughly than is necessary for the wet process. I use a circular colander with some of the holes blocked up, so that the stream of water flows from the tap through the centre. By this means a constant change can be kept up for two or three minutes, and the plate be effectually washed.

The PRESIDENT, in closing the discussion, said he was sure the meeting would pass a hearty vote of thanks to those gentlemen who had spoken. The discussion had been a most interesting one, and was especially valuable because it had been so thoroughly practical. It was one of those discussions in which seed, as it were, was laid, which at some other time would be certain to bear fruit. In conclusion the President said:—I now adjourn the meeting until October the 4th, when these walls, I hope, will be covered by works of our own production. I can only say that the session we have just terminated has been a most successful one. There has been a capital attendance of members. An excellent series of papers has been read, and cannot but tend to the progress of photography. I trust that during the summer we shall have fine weather, which will enable photographers to do work which may perhaps adorn these walls at the Annual Exhibition.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY. An ordinary fortnightly meeting was held on the 18th of April, Professor VOGEL in the chair.

Herr CREIFELS, of Cologne, sent a portrait from nature which had been executed by direct printing from the negative. The process by which this was effected was first practically applied in the Royal Government Printing Office at Berlin. It consists essentially in coating an ordinary negative with a film of chromated gelatine, when prints can be made by means of the common press. Hitherto it has only been used for reproducing linear drawings; the portrait exhibited on this occasion showed a marked advance, inasmuch as the half-tones were perfectly expressed, and the gradation well maintained.

Propos of this subject, the PRESIDENT remarked that at the present time colotype printing was being extensively carried on in America. Five gentlemen, having learned the process from Obernetter, are advertising it in America as a perfectly new process under the name of Artotype. Of course, as is the common practice in that country, the papers are making the most of it, so that those gentlemen have plenty of pupils who are rapidly extending the use of the process.

Herr VAN GRONINGEN sent from Holland the drawing and description of a drying box for gelatine emulsion plates, which, however, is nearly identical with the one exhibited by Professor Vogel at the meeting of the Society on the 21st February, the only difference being that the air, before being admitted into the box, is passed through a casing round the chimney, so that it is first heated by the flame burning in the chimney to maintain a draught, but without coming into contact with it. The air is, however, only slightly heated, as the casing exposes only a small heating surface.

Herr WROHT observed that a too highly heated current of air would be injurious to the gelatine plates. He attached great importance to keeping the temperature as constant as possible during drying.

Herr FAHLING said that in order to heat the current of air in the drying box he had kept a gas-burner alight in the admission tube, but had found that desiccation was much less expedited by this arrangement than he had expected. One peculiarity was, that the uppermost plates, which are farthest removed from the gas jet, were the first to become dry. He had also remarked that the plates prepared with Obernetter's emulsion dried quicker than any other gelatine plates.

Professor VOGEL pointed out, that by burning gas, water would be formed, and that therefore Herr Fahlings's current of air, though heated, would be charged with the vapour of water, which would fully explain its want of drying power. As regards Obernetter's plates, he quite agreed with Herr Fahlings; a glance at the list of chemicals used in their preparation would suffice to lead one to expect that they must dry quicker than pure gelatine plates. In any case, however, the best means for promoting desiccation is to dip the plates into alcohol, as has already been often explained.

The PRESIDENT showed an achromatic combination by Steinheil having a large angular aperture, an instrument which, though it is by no means unknown, had never been tried by any of the members present. When the cap is closed, it is very much like an orthoscope of about two inches in diameter; but when the objective is removed, some surprise is created at observing that the lens is not larger than a pea. The speaker expressed a very favourable opinion of the instrument; in his own experience it gives an image of from seven to nine inches in diameter, corresponding to an angle of more than 90°, quite sharp up to the outer edge. The field is, however, much larger drawing out the tube 12·1 centim.: the limit of the illuminated field on a 15-inch plate could not be discerned. Additional advantages of the instrument are, that it can be rapidly focussed, and that it gives no light spot.

The PRESIDENT further drew attention to the proposed exhibition at Sydney, and to the offer of the Government to convey, insure, and take charge of the goods of German exhibitors free of charge. He believed that it might be important for photographers to exhibit largely, as there was sure to be a good market in Australia for photographic reproductions of oil paintings and portraits of celebrities.

Herr LEYDE, of Nurnburg, sent a collection of colotype reproductions of fabrics deposited in the Bavarian Industrial Museum. They are printed in the colours of the originals, and have a very natural appearance.

Herr SCHAARWACHTER showed an imitation stone seat for use as an accessory at sittings. It was made by Mr. Seavey in wood, and bears the stamp of his well-known manufacture.

PHOTOGRAPHIC SOCIETY OF VIENNA.

A MEETING was held on the 13th of May, Dr. E. HORNG in the chair.

Dr. Steinheil, the celebrated optician, was present as guest.

After the minutes of the last meeting had been read and confirmed, and after the admission of four new members,

The CHAIRMAN announced the death of one of the original members of the Society—Herr Ludwig Angerer. He described briefly the services which the deceased had rendered to photography, and expressed, with the manifest concurrence of all present, their deep sense of the loss which the Society had experienced.

The CHAIRMAN directed the attention of the meeting to a collection of fifty beautiful photographic views in the Austrian Alps, sent by Herr Alois Beer, of Klagenfurt, and stated that the photograph of the avalanche at Bleiberg, exhibited at the last meeting by the same artist, had been presented to the Society. He also referred approvingly to a rich collection of remarkable helio-engravings, which were shown, and had been given to the Society by Herr Adalbert Franz.

Herr KRON sent for exhibition a number of cabinet views of horses in motion, taken by his new instantaneous process. In connection with this subject, the President also showed some of the instantaneous photographs of horses in motion taken by Mr. Muybridge on the race course of the ex-governor Leland Staudford, California, by means of a very intelligently-constructed electrical apparatus. He further stated that Mr. Muybridge had expressed the intention of extending his experiments to dogs and other animals so soon as he had completed some contemplated improvements, as well as of sending some communication on the chemical portion of his process.

Herr CREIFELD, of Cologne, sent for exhibition a portrait printed in a lithographic press direct from the negative, and

offered to sell his process, in case one hundred persons would each subscribe £5.

Dr. A. STEINHEIL brought forward a number of his new objectives, and expressed a wish that they might be tried by the committee of the Society, and the results of their experiments communicated to him. It was arranged that the pictures taken with these objectives should be shown at the next meeting of the Society.

Imperial Councillor MARTIN read a paper urging the importance of establishing in Austria a regular system of photographic observations of the solar surface. He had been led to entertain this project from reading in the provincial journal *Sirius* the description of a telescope which seemed peculiarly adapted for making such observations. The instrument in question was to be found in the private observatory of Herr N. Von Konkoly at O'Gyalla, in Hungary. A numerous experience had convinced this gentleman that the ordinary telescopes used in solar observations became so heated internally as to raise the temperature of the instrument some 10° or 12°, which would not fail to have a deteriorating influence on the purity and sharpness of the image. His new instrument, therefore, he had had constructed of parallel bars to replace the tube, so that the inner space was not liable to inequality of temperature. With it he could take a picture of the sun of 134 millim. diameter, and Herr Martin was anxious that M. Janssen's experiments should be repeated with the instrument. The meeting, at the instance of Herr Martin, resolved to propose this arrangement to Herr Von Konkoly.

Herr MARTIN further expressed the opinion that the production of successful photographs of the moon, would greatly contribute to the extension of our knowledge of that heavenly body. The more Rutherford's lunar photographs are studied, the more the details become apparent, and the person examining them obtains a continuously increasing insight into the constitution of the moon's surface. Unfortunately the lunar rays have a low actinic power, consequently the exposure must be an extended one. Now with the most accurately constructed clockwork for driving the equatorially mounted instrument, it is impossible on that account to prevent blurring of the outlines. It is therefore of the utmost importance to increase the sensitiveness of the plate, and Herr Martin thought it possible that Herr VON KONKOLY might allow gelatine emulsion plates to be tried in his new instrument.

A third subject of Herr Martin's communication was the employment of iron oxalate as a developer for gelatine emulsion plates. He drew attention to the fact that many years ago another salt of oxalic acid—the ammonio-oxalate of iron—had been used in photography, and he exhibited a positive taken by his friend, Dr. Glickh, by this means. A piece of ordinary paper is impregnated with this salt, exposed under a negative, and developed by floating it for a few seconds on a dilute solution of a silver salt; fixing is effected by copious washing. The speaker handed round some samples of the salt, and

Capt. TOTU promised to experiment with it in the course of the summer.

Dr. HORNIG observed that the ferrous salt of oxalic acid was used in the modern process of platinotype.

A paper by Dr. EDER and Captain TOTU was laid before the meeting; it contained an unfavourable account of the behaviour of chrysoïdin as a material for colouring the window panes of the dark room, and also a reference to Captain Abney's investigations of variously coloured glasses. Relying on the results of spectroscopic examination, a combination of aniline red and corallin was recommended for staining the globes of the lamps in the photographic laboratory, and a combination of cobalt blue and copper red glass for the window of the dark room.

Propos of a paper by Dr. J. SCHNAUSS on the results of his experiments with Obernetter's gelatine emulsion plates, a very interesting discussion on gelatine emulsion arose.

Herr HAACK stated that with some plates placed at his disposal by Herr Moll he had obtained excellent results at four o'clock p.m. on the 11th of April, in a fourth of the time that would have been required for a wet plate.

Herr JAFFE handed round several negatives, and complained of the appearance of a red fog, although both the camera and the changing box were quite impervious to light.

Dr. SZEKELY remarked that the English plates had given him unsatisfactory results; and

Herr KRAMER informed the meeting that Dr. Beck had had reason to complain of the want of adhesion shown by the English plates, but that Herr Albert was quite satisfied with them.

Herr LUCKHARDT explained that he had found the plates prepared by Obernetter himself denser than those made by pouring on them his collodion, and remarked that the necessary precaution of warming the plates is not mentioned by Obernetter. With reference to the want of adhesive power mentioned by Herr Kramer,

The PRESIDENT expressed his regret that some of the faulty plates had not been brought for examination. He also observed that the red fog had already been met with in English plates, and had been attributed by Mr. Bennett to an excess of silver nitrate.

Dr. SZEKELY mentioned that he had often observed that the film of gelatine expanded over the edges of the plate, notwithstanding the latter having been varnished.

Talk in the Studio.

THE SOUTH LONDON EXTRA MEETINGS.—In the announcement of extra meetings of the South London Society at the studio of Mr. Brittlebank, the address of the studio was, by a printer's error, omitted. We now subjoin it. No. 4 and 5, Tottenham Court Road, W.C., is the address. A successful and pleasant meeting was held last week, and on the evening of the 25th Mr. Fry was, we understand, to give a demonstration of the development of rapid gelatine plates.

GELATINO-BROMIDE PLATES.—We understand that a demonstration of the working of these plates, with practical details of intensification, and many other details, will be given by Mr. Samuel Fry on Thursday evening next, July 3rd, at eight o'clock, in the rooms of the Society of Arts, Adelphi, when photographers are invited to be present.

To Correspondents.

N. B.—Add a few drops of 20-grain solution of carbonate of soda to the bath, and shake well. The precipitate of carbonate of silver formed will carry down with it the colouring matter; allow this precipitate to remain at the bottom of the bottle, and shake up the solution with it at times. This we have found to keep a printing bath clear very satisfactorily. 2. It is somewhat difficult to mount prints on stout paper without cockling. If skilfully managed, it may be done by using very dry glue, or by using the mounting solution made by dissolving gelatine in weak alcohol. If the mounting paper be made as damp as the print, paste may be used.

W. T. SMITH.—See answer to N. B. above.

J. S.—We are not familiar with the precise cause of the defect with which you are troubled, but we are much inclined to attribute it to floating scum on the surface of the bath. If we can find any other probable cause we will answer at a future time; for the present, we have no more probable suggestion to offer.

G. B. D.—For summer use, we have always found a 30-grain silver bath strong enough for negatives, whilst for winter use we prefer a 40-grain bath. A 20-grain bath is too weak. The effect of a weak bath is to form the layer of iodide and bromide of silver on the surface of the film instead of in it, and the image is in such case at times removed in fixing.

R. M. F.—If the sensitive paper is "bone dry" when placed in contact with the negative, it is apt to give a flat poor image in printing, which no amount of toning will bring to a good colour. Of course, it must not be moist, but not absolutely desiccated.

W. S. S.—The proper remedy for crappiness in the negative is a change in the sample of collodion used. The general cause of such crappiness is the presence of too much water in the collodion from the use of alcohol insufficiently rectified. Sometimes it proceeds also from the use of an imperfect sample of pyroxyline. If it is not convenient to change the sample of collodion, matters may be mended by allowing the film to set well before immersing the plate in the bath, and rocking the plate carefully so as to secure a very even film. But the true remedy is a better sample of collodion.

F. BATHURST.—There are two or three difficulties in printing on wood for the engraver. If a film like collodion, gelatine, or albumen be used, this chips and tears up under the tool, and is very inconvenient for the engraver. Moreover, the use of aqueous solutions is injurious to the surface of the wood. The best plan, therefore, is to transfer an image to the surface of the wood, and the best transfer is one in fatty ink: a lithographic transfer, in fact. This is produced by printing a film of bi-chromated gelatine on a sheet of paper under a negative; then inking its surface with a proper roller and ink, and finally immersing in warm water. This removes the unaltered gelatine and the ink on it, leaving only the insoluble image duly inked. This inked image is easily transferred to wood by slight pressure. For full details, see some of the many articles on photolithography which we have published.

The Photographic News, July 4, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

MR. SYMONS' MIRAGE PHOTOGRAPH—WOULD-BE DISCOVERERS—THE LATE LUDWIG ANGERER, OF VIENNA.

Mr. Symons' Mirage Photograph.—We have made a careful examination of the mirage photograph which Mr. Robert Symons, of Tenby, has sent us. From that gentleman's note in these columns a fortnight ago our readers have learnt the circumstances under which the picture was secured. The weathercock on Tenby Church was under repair, and Mr. Symons, in his desire to secure a representation of the operation, the ladders and mode of ascending, the steeple-Jack, &c., forthwith brought a camera to bear upon the structure. In one of the negatives thus obtained—taken, as the photograph tells us, at 6:19 precisely—there appears an ill-defined streak just below the weathercock. You can make nothing of the streak looking at the picture in the ordinary manner, but if the spire is turned upside down, we have a clear representation of a boat. The craft resembles a life-boat in shape, for it is high out of the water, and there can be little doubt that it is a representation of such a vessel, or of a ship newly launched—floating, that is, much higher in the water than vessels usually do. From the fact that there are flags at the fore and stern, and something like bunting in the centre of the vessel also, there can, indeed, be no doubt that it is a picture of a vessel newly launched, and we think Mr. Symons may be congratulated on being the first to photograph that most romantic of phenomena, the mirage. The prow of the ship is almost sharp, and so, too, is the flagstaff at the fore; but of the flags, that at the stern is the most definite. The hull is an inch long, or, to speak more correctly, $\frac{2}{3}$ of an inch, and the stern flag must have been a very large one, since it measured $\frac{3}{4}$ of an inch. These proportions go to prove that Mr. Symons is correct in his assumption that the haze picture he has secured is the reflection of a gunboat launched at Pembroke Dock, and which, it has been ascertained, was lying upon the water at the time in question. The cloud, or vapour, over Tenby Church must have been of a nature to receive reflections, and the camera must have stood at such an angle as to receive a reflection from the direction of Pembroke Dock. Another circumstance which points to the luminous character of the vapour is the fact that on the same picture a shadowy cone—or one can almost discover two cones—which are evidently silhouettes of the Tenby spire itself. Of course, the sceptical will hesitate a good deal about the genuineness of the record, and point out—as, in fact, we did in first dealing with the matter—that there are several ways in which ghost-like photographs of this nature might be secured. A close inspection under a magnifier, as well as an examination of details, leads us to believe that the picture before us is that of a genuine mirage, while it is a fact that on many parts of our coast—near the marshy land of Landguard Fort, for instance—the optical phenomenon of a ghost-vessel suspended upside down over the real one is no uncommon occurrence at all.

Would-be Discoverers.—Every now and then we notice that some of our brethren was very clever in the matter of processes. When collodion emulsions were the order of the day, and the method of preparing them had been thoroughly detailed and explained in our columns and in those of our contemporaries, there came up certain special processes, of which the formulæ were kept secret, their advantages being stated to surpass those of the ordinary published methods. When carbon printing began to be generally adopted some half dozen years ago, glass and collodion being the chosen mediums for developing, we heard again of specially improved methods that gave people much finer pictures, and permitted

them to rely upon the tissue in a manner they had never been able to do before. We do not refer particularly to Lambert-type, but rather to the many secret plans of printing advocated by those who were rather in the rear than in the van, and who, having read time after time details in the journals, at last began to practise the thing for themselves. We were astonished at the simplicity of the process—so much so, indeed, that they could not resist the temptation to astonish others. It is now the turn of the gelatine process. The process has been fully discussed in the societies and in this journal, and if any one desired to prepare plates for himself, if he had any practice in such matters, he has merely to refer to our columns. If he wishes to purchase, there are several firms who, without making much pretence or mystery over the matter, will supply him with plates. What we desire to deprecate, however, is the arrival of late workers in the field, who have no pretensions to have originated or contributed any important modification to the production of gelatine plates, and who imagine that other people are like themselves, very backward in appreciating the advantages of gelatine bromide. By importing a little mystery into the matter, and pushing forward their own views, they doubtless imagine that the unwary may mistake them for the discoverers of the process, or at any rate for men who have at last succeeded in reconciling theory with practice. Probably there is little harm done, after all, for it is only the veriest tyro that could possibly be taken in, and in the end our plausible friends carry on the pastime for a very short time. Thus those who were loudest in recommending the universal adoption of carbon printing for small portraiture, who demonstrated its extreme simplicity on repeated occasions, and who, according to their own account, developed a couple of dozen cartes on one plate at one time, all good alike, confounding and confusing those who had been steady carbon printers for years—these hot-headed enthusiasts, we say were the first to throw up the printing of photographs in pigments, and to revert to their jog-trot method of working. So it has been, and so it will no doubt be again, though seeing how little photographers in general are to be deceived, it does seem strange that there should be any incentive to repeat the comedy so frequently.

The late Ludwig Angerer, of Vienna.—Herr Ludwig Angerer, who has just died at Vienna, and enjoyed the appointment of Court Photographer, was for a long time in the front rank of Austrian photographers. Lately, there cannot be a doubt that he has been eclipsed by Fritz Luckhardt, but fifteen years ago he was *facile princeps* in Vienna. His beautiful work, especially in the form of cabinet, attracted at one time considerable attention, and he was, we believe, the first, or one of the first, to whom the Emperor extended his favour and patronage. Herr Ludwig Angerer had considerable faith in the employment of coloured rays reflected on the model during the exposure of the plate, and made several experiments with a view to shortening the time of sitting. His results led him to believe firmly in blue rays, and he went so far as to have a large studio erected, fitted entirely with blue glass. We had the pleasure of visiting this studio some years ago, and although we could not but testify to the softness and harmony of Herr Angerer's work, we had considerable doubt as to the charming qualities in the pictures being due to the azure illumination on the subject. Indeed, we rather think that Herr Angerer afterwards inclined to the belief that no advantage was gained by his blue panes of glass, although they certainly had no detrimental effect, as his pictures bore testimony. Herr Angerer took little interest in matters outside his own occupation, and rarely, if ever, spoke at the meetings of the Vienna Photographic Society; neither, do we think, did he contribute to photographic literature. He was, however, highly esteemed among his brethren as one of the most capable of photographers of the *Kaiserstadt*.

THE SINGLE TRANSFER PROCESS FOR SMALL WORK.*

HAVING the power by means of the reversing mirror to produce negatives which can be printed by the most simple of all processes, viz., the single transfer, a short account of the operations will at once show how easily and rapidly permanent photographs equal to silver prints may be produced.

The mode of making the tissue sensitive to light is so well known, by means of the instructions sent out with every band of the Autotype Company's tissue, that it will not be necessary to do more than to call attention to the necessity that exists for satisfactorily drying it after sensitizing. The best drying room is undoubtedly an apartment warmed by an ordinary English stove, which, giving the smallest amount of heat with the greatest amount of ventilation, is exactly suited for drying tissue; if a fire has been burning in the stove during the day, and allowed to die out in the evening, when the sensitizing of the tissue generally takes place, the arrangement will be perfect, and by the next morning the tissue will be in a most excellent condition; should, however, it be inconvenient to have a fire, one of those gas stoves known as "cheerful gas stoves" will answer admirably; one can be bought for about a pound, and if the flue-pipe is taken just into the chimney, all the fumes will be carried away, and a gentle dry heat with a proper amount of ventilation be secured for any length of time.

Having the tissue properly dry, the most important thing now is to keep it so. Whatever speculations there may be as to the causes of insolubility in tissue, they may be all summed up, if the tissue is properly made, in two words, *light and damp*. If tissue is kept from the light, and prevented from absorbing moisture, it will remain perfectly good and soluble for weeks: as far as light is concerned, it requires about the same care as silver paper; as far as damp is concerned, it requires far more; the precautions to be taken are simple enough, but they must not be neglected.

When the tissue is taken down, after being thoroughly dried, it should be cut up into convenient sizes and placed in a tin tray made with a heavy lid to drop just inside the tray, on the same principle that tobacco is kept moist in the old-fashioned lead tobacco pots. The lid may be made of dry wood, and a piece of stout sheet lead or zinc screwed to the underneath side (the screw heads must be countersunk, of course); this lid will go inside the tray, and, being weighty, will keep the tissue pressed flat and the air away from it; the lid should have a strong knob or small handle on the upper side. In such trays, the tissue should be kept both after sensitizing and after exposure to light under a negative, if the development does not take place at once. In addition to this, the printing-frames must be dry, dry blotting-paper should be used as pads, and care be taken that it does not get damp: it should be taken out, and it and the frames put before a fire occasionally, especially in damp weather.

If these three points are attended to—viz., to thoroughly dry the tissue, to keep the tissue dry, and to have dry pads and printing-frames—carbon printing has no difficulties; if these are neglected, the production of uniform and good prints is hopeless. The action of the light upon carbon tissue being invisible, the progress of the picture cannot be observed from time to time as it can in silver printing, and this might appear a startling difficulty; it is not really a difficulty at all, for, by the use of the photometer, which is put out at the same time that the negatives are exposed to the light, any number of photographs may be accurately printed when the operator has had a little experience in marking the negatives with the tints they require. Mr. Woodbury has just brought out the best and most ingenious photometer that has yet been introduced.

* *Autotype Notes.*

The pieces of tissue being printed and in their tray waiting for development, the next operation is to place them in contact with the paper upon which the picture is finally to rest. This paper is called single transfer paper, and is sent out by the Autotype Company in bands of 12 feet in length and 30 and 36 inches in width, suitable for large work; and a very fine paper in sheets, about the size of albumenized paper, having a beautiful surface and specially adapted for portraits and small work.

The first operation is the transfer for development. To effect this, the insolated tissue is immersed in cold water, together with a piece of the single transfer paper somewhat larger than itself; the two surfaces are applied to one another under water, and both drawn out together the moment the tissue loses its rigidity; the effect of which is to bring the surfaces into contact without air-bubbles intervening. They are then placed upon the sheet of zinc, the tissue uppermost, and the squeegee applied as follows:—Place two fingers of the left hand upon the edge of the paper, and with the india-rubber scraper or squeegee in the right hand, with a motion from left to right, *scrape* out the water from between the surfaces of the pigment paper and plate. Do this two or three times, if necessary; then repeat the operation in the opposite direction, so as to drive out all the air from between the surfaces. This can be done with perfect certainty after a little practice; but if it be not done thoroughly, the process fails. When the sheets have been thus forced into intimate contact, they should be placed between bibulous boards for a few minutes, or may be hung up to a string with American clips; by the time about a dozen pictures are thus transferred, the first ones will be ready for the next operation, the development.

This is effected by immersing the united papers in one of the trays filled with water, the temperature of which may be from 90° to 110° Fahr. In the course of a few seconds a partial solution of the gelatine compound will take place, evidenced by portions of the coloured gelatine exuding from the edges of the pigmented paper: when this occurs, the paper upon which the pigmented tissue was supported may be gently drawn away from the transfer paper, which will be left with most of the coloured compound adhering to it, and presenting the appearance only of a black, slimy-looking sheet. If the water then be allowed to pass over the surface, lavng it gently with the hand, the picture will gradually appear as the excess of colour is dissolved away. If the exposure has been correct, the picture will appear with all its details to perfection.

Errors in Exposure.—If the exposure has been too long, the gelatine compound will dissolve with some difficulty, and the resulting picture will be heavy in the shadows, and the lighter tones will be wanting in clearness. If, on the other hand, the exposure has been insufficient, the compound will dissolve away quickly, leaving the developed picture bare and chalky in the high lights, and lacking vigor in the shadows.

Of course a proper exposure ensures the most perfect result, but there is an advantage attending this process, that an under or an over-exposed picture may be made fairly presentable by modifying the development, using hotter water than usual in the case of an over-exposed print, and which may be further reduced by soaking for a short time in water at a higher temperature; and, on the other hand, an under-exposed print may often be saved by removing it, when partially developed, from the warm water, and continuing the development in cooler water.

The picture should always appear a little lighter in the water than it is wished for finally, as it dries up a shade or two darker. The development being completed, the print should be transferred to another trough filled with cold water, which at once arrests any further action upon the gelatine, and it is now ready for the fixing.

Prints thus produced do not really require "fixing," using the word in its proper sense, as the picture, being produced

by the formation of insoluble gelatine, would not be liable to any further change whatever; but in many cases some of the sensitizing salts are left in the paper, which mere soaking in water does not readily remove.

To effect the removal of these salts, place in an earthenware pan a solution of common alum of the strength of one part of alum to thirty parts of water, and allow the print to remain in this until every particle of yellow colour caused by the excess of chromic salt has entirely disappeared; the alum solution, having a very strong solvent action upon the chromic salt, will soon accomplish this; but it is very important that this operation should be fully completed, otherwise the germs of deterioration and decay are certainly left in the print. Allow the print to remain in the alum some time after the yellow tint has disappeared, then transfer it to another tray containing perfectly clean cold water, allow it to remain long enough to wash all trace of alum out of it, then rinse with a little cold water, and hang up to dry.

It will thus be seen how really facile is the process of carbon printing in its simplest form; the pictures, when dry, can be mounted, spotted, rolled, or burnished exactly like silver prints. If a very high gloss is desired, similar to an enamelled silver print, it is very easily obtained by waxing a plate of glass, coating it with enamelling collodion, washing the ether and alcohol away, and upon this laying down the carbon print whilst it is wet; if this is mounted whilst still on the glass, as enamelled pictures are, it may be stripped off when perfectly dry, and will have a most perfect and brilliant lustre.

In practice there are two things that a carbon printer must specially attend to, first, to thoroughly dry the tissue; and second, not to let it get damp again until it is placed upon the transfer paper.

A NEW METHOD OF MEASURING THE CHEMICAL INTENSITY OF THE SOLAR RAY.*

In a recent paper read at a meeting of the American Chemical Society the presiding officer, Dr. Leeds, gave the results of a series of experiments upon the department of metallic iodides, other than the salts of silver, and while his investigations are more especially of interest to chemists, yet they involved certain points which illustrate some of the phenomena of photography, and possibly may have a bearing upon future development in photographic art. It is probably a fact known to many photographers that the test for the presence of nitrites and chlorine in solution consists in the addition of some soluble iodide, usually that of potassium, together with some starch, when if either of the above-mentioned bodies are present, a blue colour will be developed, the time of whose appearance and its intensity depending upon the amount of nitrous acid or free chlorine in the liquid under examination. Frequently it is of great importance to determine whether the hydrochloric acid sold by the manufacturer as chemically pure contains free chlorine, or the nitric acid, C. P., contains nitrous acid. This is almost always the case if the nitric acid has been for any length of time exposed to light. In the course of such an examination, 1 c. c. of the acids being diluted with 1 litre of water, and 1 c. c. of a 10 per cent. solution of potassium iodide and 5 c. c. of starch water added, Dr. Leeds noticed that the amount of iodide of starch formed varied in different trials with the same acids, and that after the solution had been decolorized by a standard solution of sodium hyposulphite, they again acquired a blue colour on standing. In one series of experiments, this repeated liberation of iodine went on from Oct. 27th to Jan. 3rd, the solutions being decolorized by the hyposulphite thirteen times during the interim. It is hardly needful to state that the iodide used

was made with great care, and contained neither free iodine or any alkaline iodate.

These unlooked-for results gave rise to the suspicion that the light played a part heretofore unsuspected in the operation of these tests. To verify this hypothesis, parallel series of solutions containing to 1 c. c. of potassium iodide, 1 c. c. of sulphuric acid (free from nitrous acid) and 5 c. c. of starch, 20, 50, 80, 100, 150, 250, and 500 c. c. of water, were prepared and placed one half in total darkness and one half in sunlight respectively. For a long time the results of these trials did not agree very perfectly, although there appeared to be in both cases a distinct law governing the amount of change. In the dark the amount of iodide of starch formed was as the degree of concentration, the 20 c. c. solution containing most at the expiration of twenty-four hours, while the 500 c. c. solution was scarcely, if at all, affected during the same interval. In the sunlight colouration began at the end of a few minutes, and at the expiration of half an hour most or all of the starch present had been precipitated in the form of iodide. The law of decomposition appeared to follow the degree of dilution in this case, the amount of iodide set free being greatest in the solutions which were weakest. The contradictory results, however, disappeared when comparison tubes of uniform bore, and made of the same kind of glass, were substituted for the bottles of various make, sizes, and forms at first employed. When this was done, the amount of change was rigorously proportional to the dilution, or, in other words, to the volume, which again, in tubes of uniform bore, kept always at right angles to the solar ray, would be directly as the surface of exposure. Furthermore it was found on trial, what would naturally be inferred from the foregoing, that with solutions of the same degree of dilution, the amount of change was directly proportional to the length of exposure to the sun's rays when the intensity of the sunlight was constant, or directly as the intensity when this experienced an increase or diminution.

Upon these laws a new method of actinometry has been founded. The usual method, originally proposed many years ago by Dr. John W. Draper, of New York, and afterwards elaborated by Profs. Bunsen and Roscoe, consists in determining the amounts of hydrogen and chlorine gases which are made to combine by the solar ray, or other source of illumination possessing a sufficient actinic power. This beautiful method has the disadvantage of requiring complex apparatus, and of necessitating great skill in manipulation. To determine, in the method proposed, the amount of iodine set free can be rapidly performed according to familiar modes of volumetric analysis.

[A tabular illustration of the mode of working out this process follows, which it is not necessary to reproduce here.—ED].

SELECTIONS FROM THE DIARY OF AN ARTISTIC PHOTOGRAPHER.

BY J. P. RANDOLPH.*

I HAVE often wondered why the photographic fraternity in general have not given more attention to instantaneous photography; which branch, if properly prosecuted and in the right direction, will pay better than can be imagined. The principal drawback to this line of business is, as far as I can learn, the want of sensitiveness in the chemicals, and some *modus operandi* of shutting off the exposure in an instantaneous manner, as the name would imply. Now, I have given this much study, and have had some experience, and I propose to lay down certain rules and give formulas for preparing chemicals that have not failed to work with very good detail, instantaneously in every sense of the word; when I say instantaneous, I do not mean one, two, or three seconds,

* *Anthony's Photographic Bulletin*.

* *Photographic Rays of Light*.

but of sufficient rapidity to photograph a trotting horse travelling at a rapid gait. Should all follow my directions explicitly, they cannot fail to do likewise.

At a certain period in my life I made viewing, or outdoor work, a speciality, and, of course, had many different models to photograph; but the case which I propose to lay before your notice is simply the following:—

I was working in Lexington, Ky. My principal business was landscape photography, which, as I have said, I made a speciality. One day, a gentleman came to me and desired a picture of the celebrated trotting nag, "Lady Drew," said picture to be made while the mare was trotting at a smooth gait, in harness, to a sulky. This was rather a hazardous undertaking, nevertheless I repaired to the race-course on the first bright day. The track was of circular form, one mile around, and as level as any floor. I set my instruments just sixty feet from the track, with the sun to my back, which, of course, would then shine upon the subject. I then had the jockey to ride up on the track in front of my lens, and stop until I procured the focus. After doing this, I particularly cautioned him to drive as near the same place, from which I focussed, in passing my lens, during exposure, and also to hold the reins very tight, so that the head of the animal would be in the proper position, and have the same motion as the body.

I then coated an 11 by 14 plate with a collodion prepared as follows:—

Alcohol	2½ ounces
Iodide lithium	16 grains
Ether	1½ ounces
Bromide lithium	7 grains
Cotton	6 "

After which, I immersed the plate in a bath which I prepared as follows:—

Pure nitrate silver	1 ounce
Distilled water	13 ounces

Iodize with iodide of silver prepared in the ordinary manner, and add two drops of C. P. nitric acid to each thirteen ounces of solution. This bath and collodion harmonize well, and give beautiful results. The plate must be immersed in the bath not less than four minutes. I now adjusted my shutter or exposing slide, which is very simple, and made as follows:—

Procure two pieces of scantling three inches square, so that when standing upright with one end on the ground the other end will rise about six or eight inches above the top of your box. Attach feet to these uprights, similar to a screen stand; now in these uprights smoothly cut a groove so that a polished walnut board will slide along the groove without impediment; allow the grooves to run from the top of the uprights to within six inches below the mouth of the lens. After doing this, place it in front of the instrument, leaving one inch space on each side of the lens. Now fasten together both at the top and the bottom; simply nail a cleat on one side, at the top; at the bottom, on both sides, thus making the stand very solid. The next operation is to procure a half-inch walnut board that will slide in the grooves before mentioned: this board must slide smoothly and with rapidity, when started from the top of the grooves. The length must be governed by the height of your box. When the board is at the bottom of the grooves, the upper part must cover the mouth of the lens, and *vice versa*, and must be close enough to slide in simple contact with the brass-work, but not so compact as to cause the box to be disturbed when the slide is in motion. The opening to be cut in this board must be according to a person's desire to give short exposure to the sky. A triangle with the broader portion at the bottom will act satisfactorily. A round opening, the size of the mouth of the lens, will give an equal exposure. To procure grand cloud effects, cut a

half circle similar to a half moon, with the larger or oval part at the top; this gives short exposure to the foreground. The half circle must taper to a point at each end, pointing toward the ground when in the grooves. Now procure an article of wire that will not too easily bend, and of sufficient length to reach from your box to the track, at an angle of forty-five degrees, on the side of your upright exposing stand. Screw several large hooks, similar to screw eyes, run the wire through these hooks to the top, then bend it in a square manner so it will reach the centre of the walnut board that slides in the grooves. In this board fasten a small hook, so that when the wire is holding the board in the proper position, and at the least movement of the wire, the hook will be detached and the drop will fall. Now run the wire to the track at an angle that will cause the horse and sulky to be on a parallel line with your lens when the fore-wheel of the sulky strikes the wire. As the wheel strikes the wire the drop will fall, thus giving an exposure without assistance.

The horse must be a sufficient distance from the place of exposure in order to allow the animal to procure a smooth, easy, and steady gait. The proper position in which to place the wire on the track can easily be ascertained by experimenting with the horse and sulky before exposure. This is the most useful method that I have ever tried, and I am positive it has never before appeared in print. For photographing cars or locomotives, the wire must be dispensed with, when the hand acts as the dropping medium.

The developer I use is the finest I have ever tried. By experimenting with different formulas I think I have found the bona fide article. It is prepared as follows:—

Proto. sulphate of iron	1 ounce
Sugar of lead	12 grains
Water	7 ounces

Dissolve altogether, and filter.

Now make the following solution:—

Formic acid	1½ ounce
Nitric ether	3 drachms
Acetic acid	2½ ounces
Acetic ether	2½ drachms
Epsom salts	4 grains

Mix this solution well, and add to the former. It should be made up but a few hours before using.

In order to be successful in this branch of photography a person must exercise a great deal of patience, and must have good judgment as to the proper kind of weather. The instruments must be a matter of paramount consideration. Pure chemicals are absolutely necessary; they should also be fresh. The instrument with which I made this picture, was an 11 by 14 wide-angle view lens—short focus—a cone box of the same size. These lenses are quick-acting, and are well adapted to this business.

During the year 1871 I was unexpectedly called to my home in Virginia by the sickness of a sister. I remained until she was convalescent, when, taking the back track, I stopped over a small town where I had some acquaintances, with whom I intended remaining a few days. Strolling through the town the day following my arrival, my attention was attracted by a sign which read, "Photograph Gallery." I at once went upstairs to see "our brother." The proprietor, principal and sole operator, was a young man seemingly some sixteen years of age. After introducing myself, I inquired how business prospered. He said, "Business would be good enough if I could only get in running order." I inquired into the nature of his trouble, and soon learned that his chemicals were all out of order—in the true sense of the word, in a "fog." I glanced at his work which he had been trying to do, which

was poor enough. I expressed a willingness to assist him, which caused him so much joy that, for the moment, I thought he would embrace me. The first thing I did was to make an exposure. When the negative was brought to the light, I beheld a mixture of streaks, blotches, and zig-zag lines, similar to the ripples on a lake. There were, besides, little oblong, densely opaque patches strewn about over the plate. But the most curious part to him was that just as soon as the water was turned on after fixing, the image entirely disappeared. There were also indications of fog. "Now," I remarked, "I will explain all of this to you, and give a remedy for each of these blemishes. We will then try my remedy, and see if I am not correct. Pay good attention, for then, should you ever get into this scrape again, you can easily rectify it.

"These little zig-zag lines, which you see run in the direction the plate was dipped in the bath, were caused by immersing the plate before the collodion was properly set. These little opaque patches were caused by the undissolved ingredients in your collodion—poor alcohol and worse cotton. These streaks are caused by your bath being neutral, or alkaline, too much so for your collodion, which also caused the fog."

"But what makes it wash off in that way?" he asked.

"That is very easily explained," I continued. "Get your hydrometer, and test the strength of your bath. Well, now, how strong is it?"

"It is just seventeen grains strong," he replied.

"How did you make your collodion?" I inquired. He produced his formula, which is a very good one for all kinds of work, and I will here give it, for it will never fail to work:—

Aleohol	15 ounces
Ether	15 "
Iodide ammonium	80 grains
Bromide potassium	50 "
Bromide ammonium	25 "
Iodide cadmium	80 "
Bromide cadmium	50 "
Cotton	150 "

I then inquired how he dissolved his potassium.

"In a little water," he said.

"You have used too much water where you should not have used any. Not being used to making collodion, I would advise you in the future not to make your own collodion, but buy it from some good stock dealer, and then you will know it is good. Now we will evaporate your bath to dryness, fuse it, make some new collodion, and you will be all right. If your bath had been strong enough, the film would not be so rotten. Hence, that is one reason why it disappears from the plate during the process of washing."

With that we went to work, and made some new collodion by the above recipe. After doing this, I called for his evaporating dish.

"My what?" said he.

"Your evaporating dish," I repeated. "Your round porcelain dish which you boil your bath in."

"I don't know what it is, sir; never saw one in my life."

I was fairly surprised at this. "Don't you read the journals?"

"No, sir; I have never read but one, which I found among the things when I bought them."

I told him I would send him some when I got home.

The best thing I could do, under the circumstances, was to procure an iron pot lined with porcelain, which, I think, in many respects, is equal to the genuine article until it becomes fire eaten, when it makes a good lye pot for glass.

After getting his dark room in good working order, I

next looked into his printing room. He said he had a great deal of trouble with his paper.

"It has specks all over it. What is the cause of it?"

I looked at his paper after being silvered, and found there were little pink specks all over the surface, and that it presented a mottled appearance.

"This," I said, "is caused by a weak bath and under fuming. Always keep your bath forty grains strong, and slightly neutral. In warm weather, silver one minute and a-half; in cold weather, silver two and a-half minutes; fume from fifteen to twenty minutes. If your bath is forty grains strong, and your paper presents this mottled appearance, you have not fumed long enough. So now you are in good trim, and I will bid you good day."

That same man is to-day one of our most successful photographers.

It is the duty of all employées to seek the advancements of their employer's business, for in so doing they but advance their own. An employer will readily discover and reward all tendency on the part of workmen to endeavour to do their best. Keep the gallery neat and clean, dust off the frames, be polite and attentive to all customers, do not be slovenly in your own personal appearance; in fact, do everything with a faithfulness as if you intended to remain there the balance of your days. I have frequently beheld a tendency on the part of employées to slight their work, not caring what became of their employer's reputation, thinking if they were discharged they could easily procure other situations. Now this is wrong and unjust, for you had as well put your hand in his pocket and take his money as neglect his interest.

I admit that some employers are task-masters, and unjust toward their workmen, expecting more from "a hand" than he can accomplish in an artistic manner. I worked for one of this species of the human race at one time. There were three of us. I will relate a little circumstance that happened while in his employment. It may serve to show up one of the "tricks" sometimes practised in our art.

We had to make a picture of a corpse, at the residence—a little child. After making the negative we brought it back and gave it to our employer. It was in summer. The window being raised, he stood it against the casing to dry. We went on with our work, when all at once we heard a crash. Up came the "boss" in a purple rage.

"Twenty-five dollars lost through the carelessness of workmen! There is no dependence to be placed in them," he said, when he had placed it there himself. "Now," said he, "if you men don't patch that negative up and make a good print from it, I will make you all pay for it."

"We did not like this, for he was behind with us in salary, so had the advantage. I gathered up the fragments with a sorrowful heart, and with a countenance ten dollars less pleasant than a few moments previous, when, to my joy, I beheld one piece of the glass, bearing the head, face, and neck, sound as a dollar. Our way was easy now. We proceeded as follows:—Selecting an old negative from among the corpse negatives we then had on hand, as near the same size of the broken subject as possible, we then took a sharp, keen knife, and removed the face of the subject, so that the broken film would fit it nicely. After removing or scraping off the head, we removed the film from the broken negative by soaking in water, with the assistance of gelatine. After trimming and re-trimming, we at last secured a very nice fit. We then varnished the new negative, opaqued the background to hide all blemishes, and then printed; after printing, we grayed the ground. All children, when in death, have their hands folded over the breast, hence we had no trouble in this respect.

OLD AND MODERN MODES OF TONING.

To those who are familiar with the history of photographic printing and the changes which have taken place in the practice of silver printing, it will seem somewhat strange to enter, at this day, into any discussion or estimate of the relative value of gold toning pure and simple as at present practised, and that of the old hypo toning bath. We receive continual evidence, however, that some renewal of the subject is not entirely unnecessary. Not unfrequently, we find old photographers referring to the old system with regret that it has been entirely abandoned. And, occasionally, we find young photographers who only know of the old method by tradition, anxious to know why it was abandoned. We have before us a letter, which, if we were disposed to deal with the subject in a "chaffing" spirit, we might mention as dated "Hauwell" (!), in which the writer states that he has been informed by a friend—an old photographer—that a bath of hypo and gold, containing fifteen grains of chloride of gold in two quarts of saturated solution of hyposulphite, toned more rapidly, saved every grain of silver, and gave as good results as the present method. He naturally presumes that there must have been some good reason for the abandonment of such a process. The conclusion is a very legitimate one; and as we frequently meet with similar queries which cannot be fully answered in the column devoted to answering correspondents, we may briefly restate the case here.

Prints placed in the "old hypo" bath, in which the processes of toning and fixing went on together, inevitably underwent a process of sulphur toning. If an unwashed print be placed in a solution of hyposulphite, the free nitrate of silver present inevitably decomposes a portion of the hyposulphite, liberating sulphur and producing sulphur toning; and sulphur toning, as experience quickly taught, was unstable, producing fading prints. To avoid this the plan of gold toning was devised. The print was to be toned by a deposit of pure gold, and then subsequently fixed in a solution of neutral hyposulphite, and properly washed. Theoretically speaking, if this process were carried out with precision the prints should be permanent. The sad fact that they are not always permanent is probably due to many causes, the chief of which is doubtless to be found in the fact that the processes are not always carried out with proper care. But it is something, surely, to have a process which should theoretically give permanence in place of a method which was exceedingly uncertain, but certainly untrustworthy.

The old hypo bath was a strange mixture, and constantly changing in its character. Decomposition was initiated at the outset, and fresh decompositions were constantly going on ward; and the older it was and the more full of uncertain abominations, the more rapidly it toned, and the more

valuable it was considered. It was a great step in the direction of theoretical propriety when the use of the separate gold-toning bath was adopted. And if it has not resulted in greater certainty of permanency, it has been due to the causes in operation not entirely under the photographer's control. At best, silver is not a very stable substance, as every silversmith's assistant knows when he cleans from time to time his master's tarnished stock. And hyposulphite is a treacherously unstable substance, decompositions often being set up in the fixing bath, unknown to the photographer, which finally issue in changes in the print. Fortunately, more stable processes are now in existence, and are daily acquiring a more practical character, and promising to supersede prints which, under the best conditions, are of doubtful permanency, by rendering the production of permanent prints easy and certain.

COLOURED MINIATURES ON GLASS.

ENGLISH photographers have been familiar for many years with methods of colouring photographs at the back, and then rendering the paper transparent, so that the colours being seen through the print give the effect of a skillfully coloured picture to work very roughly done. In some of these processes the print is mounted on before colouring, and, when completed, the effect is obtained of a miniature on glass, plain or convex. A method which has recently been patented in America appears to be very perfect in its details. Some of our American friends believe that the method has been published previously in this country, and that hence the American patent is invalid. We now publish the American specification. If any of our readers are familiar with such a process in all its precise details we shall be glad to know where it was published. In any case, the detailed precision of the American specification will be interesting and useful to many of our readers, as it is not patented in this country. The patentee is Mr. B. T. Irish. He says:—

"My invention relates to the production of coloured pictures by mounting a photograph on glass, removing the paper, so as to render the print transparent, and then colouring the picture on the back. This method has been practised for many years with more or less success; but as heretofore practised it has been difficult and uncertain, and the results obtained have not been considered artistic.

"My invention consists in certain improvements on the method referred to, which result in the obtaining of effects superior to those obtained by any other system known to me.

"I shall first describe my process or method in detail, and will then point out those features which distinguish it from others.

"The photograph, if mounted, is first removed from its card by soaking for a time in water, and then peeling the card away from the photographic paper. The unmounted photograph is now attached by its face to a glass by means of a paste made of—

Water	10 parts
Starch	4 "
Nitrate of strontium	1 part

stirred, dissolved, and boiled until the mixture has cooked well.

"Other pastes or materials, however, may be used to attach the photograph to the glass, if desired. The paste above described is one good material for the purpose.

"After the photograph is affixed to the glass, as stated, it is left until all moisture has dried out of it, and the paper is then made transparent as follows:—The paper is ground down until it looks quite dark and very thin, or, possibly, until the surface film next to the glass begins to be very slightly scratched. The grinding is effected by emery-cloth, or fine sand-paper, or the like, with which the back of the photograph is rubbed briskly until the paper is nearly ground off from the glass. When it is thus ground suf-

ficiently and evenly, it is placed in a bath of melted paraffin, for which other substances, such as bees-wax or spermaceti, may be substituted. It is there left for a few moments, and is then removed, and all surplus wax is rubbed with a cloth from the back of the picture. It cools immediately, and is then clear and transparent, and ready for colouring or painting.

"This method of rendering photographic paper transparent, and preparing it for colouring or painting, is a decided improvement over any system heretofore devised. The improvement is due to the conjoined operations of grinding and treating the paper with paraffin-wax or its equivalent.

"I am aware, as above said, that it is not new with me to remove the greater portion of the body of the mounted paper; but I am not aware that this has ever been before effected by grinding down the dry paper. Nor am I aware that the grinding operation, or, indeed, any method of removing the paper, has ever been used in conjunction with the wax treatment. I exclude from the category of wax the balsams, oils, and varnishes which have been used for the purpose of giving the picture transparency. These materials are not to be relied on, are difficult to use, and are objectionable in other material respects, since they are certain to ruin photographic prints by causing them to turn yellow, to spot, or to crack from the glass.

"My process gives to the photograph the appearance of a transparency upon ground glass, of a dull or softened appearance, and of such density as will admit of colours showing through the picture with a softness, and yet brilliancy, not attained by any other method of which I have knowledge.

"In addition to the beauty of the effect, further advantages are derived, in that there is freedom from liability to spot, or to become injured by dust, moisture, handling, &c., and durability of the transparency and picture is obtained.

"After the photographic print has been rendered transparent, as described, it is then painted with oil-colours; or such parts as may be desired are touched up direct upon the back of the picture itself. Then another glass is placed at the back of the picture, and oil-colours are put upon the back of this second glass, and the various tints are placed opposite such parts of the picture as may be desired. Thus the colours are separated from the picture by the thickness of a glass, and this separation of the colour has certain advantages over painting direct upon the back of the picture, as greater softness can be obtained in this way; consequently, it is really a system of double painting. When the painting is completed, the glasses are backed with a piece of card-board, and the whole is then bound together with strips of gummed paper, and the picture is finished.

"Having described my invention, what I claim, and desire to secure by Letters Patent, is—

"The process of preparing and producing coloured photographs on glass, by first mounting the photograph on glass, face downward, then grinding it thin from the back, and then treating it with paraffin or its equivalent, as specified, or the after reception of oil-colours, applied directly to the back of the picture, or to a second glass, to be applied as a backing, substantially, as herein described."

FRENCH CORRESPONDENCE.

PHOTO-ENGRAVING PROCESS IN PRACTICE—FUTURE USEFULNESS OF PHOTOGRAPHIC SOCIETIES.

IN the PHOTOGRAPHIC NEWS of the 13th June, among other interesting subjects, there are two articles on which I should like to say a word or two. The first of these is entitled "Photo-Engraving Processes in Practice;" the second, "On the Future Usefulness of Photographic Societies."

Photo-Engraving Processes in Practice.—I have thought it advisable to transfer to the columns of the *Moniteur*

de la Photographie the article on phototype printing, with the addition of some rather copious comments of my own. My reason for doing so is, that this question, as it appears to me, is one of the most important of those which are met with among the many applications of photography. I may be allowed to give here a condensed account of the ideas suggested to me by the author of this able and truthful article. What he says as to the impossibility of converting by some known photographic process any kind of original drawing into a printing block—that is to say, into a plate with prominences and depressions, of which the raised portions will give an impression—is absolutely true, and will remain so until some method is discovered of printing simultaneously with the type a photographic image in which the gradation of the shading and the fineness of detail are equal to those of an ordinary photograph in silver salts, or one produced by the process designated phototypie (collo type). As I have made use of this word, I may draw attention to the fact that it is the designation of one of the processes by means of which, according to the author of this interesting article, photo-typographic printing may eventually be rendered successful. "By surface printing," he says, "as in collogotype, a block may be secured; but this is not to be worked in a printing press." The whole of my personal experience on the subject of the process of phototypie, as I have published it, is thus entirely corroborated. Phototypie, as is truly said, might be used for taking photo-typographic impressions of this process, or rather of the plates produced by this process, which could be printed in the ordinary printing press. Most certainly, in the present state of the collogotype process, there would be plenty of difficulties to overcome before that could be the case. We cannot imagine it to be possible, working the process as it is everywhere worked, to insert in the text plates with margins projecting all round beyond the picture, while for a typographic print it is essential that all the blocks should have the dimensions of the image itself, otherwise their insertion in the text is perfectly impracticable. To cut the plates, bearing the printing surface on a film of gelatine, to the required dimensions must not be thought of: this course is neither possible nor otherwise practicable, and is, besides, anything but economical. But I have pointed out a method, as I think, of turning the position, so that the production of collogotypographic blocks will become feasible. From the present time, as my preliminary experiments go to prove, the problem of photo-typography may be considered solved; it is now only a question of putting it into practice—not that I mean to say that the latter is an easy question at all. In the comments on my translation of the above-mentioned article, I have asserted my absolute conviction that the collogotype process is the only one—at least, in the present state of our knowledge—by the aid of which we can arrive at the solution of this important problem. With metal plates we can only succeed when the lines or grain forming the shading or modelling are very close together, and the result is an unpleasant and unclean aspect, which is anything but artistic. A grain in line, however fine it may be, cuts up the subject and separates it into confused parts; for instance, the eyes, the nose, the mouth, of a portrait are nothing more than a patch-work formed by a sort of weaving of lines or granulations which form a distance, renders the whole effect agreeably; but viewed closely appears as a cross-hatching, sometimes anything but satisfactory. It will be noticed that it is only possible to print from plates like these in the printing press when the granulation or lines are sufficiently wide apart, otherwise the white spaces will be smudged, and the impression will be entirely spoiled. If we examine any wood engraving we shall see that, however subdivided it may be, however much it may be hatched, wherever necessary, it gives a finite outline, the gradations of shading are rendered by a more or less close grain; but the eyes, the mouth, the nose, instead of being cut by white spaces, are

formed by clean-cut and continuous lines. The air is also clearly outlined, an effect which an intelligent hand is able to interpret, but which a mechanical and unintelligent process can never produce. I have seen some printing blocks made by M. Petit, who is the photographic operator of the house of Firmiu-Didot. He rules, by means of a machine, a regular grained pattern in line over a negative plate, and by crossing the cuts of this pattern he obtains a print, which a certain amount of retouching by hand on the zinc succeeds in making passable, but which, in my opinion, is far from realising the object that we are in search of. What we want is a block to be inserted in the text, and capable of being printed from simultaneously with the type; the block, without any cutting whatever, must have on it a picture similar in every respect to an ordinary photographic print. Now this, I repeat, we are only likely to obtain by the process of phototypie; in this process alone shall we find the solution of a problem which is destined to exercise so important an influence on the future of the applications of photography. I refer the readers of the PHOTOGRAPHIC NEWS to my article published in the *Moniteur de la Photographie* of the 1st of June last, under the title of "New Process of Phototypie," where they will learn what I have been able to accomplish in this direction, and will obtain some idea of a new improvement in this method of photo-typographic printing.

On the Future Usefulness of Photographic Societies.—I have been much struck by the paper on this subject read by Mr. Arthur Brittlebank before the South London Photographic Society. The position which, as he maintains, photographic societies ought to occupy is a very high one, and the idea of a technical institute for photography controlled and directed by such societies—an idea which he elucidates very happily—is worthy of great praise. He gives a number of reasons for holding that the time is now come for photography to be regarded as a science, for providing it with means of instruction, so that those who embrace it as a profession should have a sufficient knowledge of chemistry, optics, and the rules of art generally. Such an institution appears to be wanting in England, and we in France are no more richly endowed in this respect. My own opinion is that it would be exceedingly difficult to create in this country a special school for training capable and skilled operators; but what I think would be easier would be to organize in the larger photographic establishments a general system of instruction in all the branches of science and art bearing on a sound and intelligent practice of photography. But however that may be, we all here agree fully with Mr. Brittlebank's views, and we should be glad to see them carried out in England, because it would be for us an excellent example, and also a great incentive to establish in France a special institution of the kind indicated. For the present we are fain to be content with courses of lectures on photography. Such a course I have myself professed at one of our art schools, and I shall probably renew it; M. Davanne, again, has made an essay of the same sort at the Sorbonne. These are only the thin end of the wedge, for instruction so limited as this must be quite insufficient to meet the wants of a profession which numbers so many members. There are in Paris more than 2,000 photographers; if we add another 2,000 for the provinces, we shall have a total of 4,000 persons engaged either as principals or assistants in the practice of photography; and all these, as well as the art itself, could not fail to reap great advantages from a proper system of technical instruction. In England the number of persons who have taken up photography as a profession is still larger, and the need of obtaining for them systematic training in chemistry, optics, and art is in proportion greater. My own humble need of approval is not of a kind to give any additional value to Mr. Brittlebank's admirable proposals, but it is as well that he should understand, and that all your readers should know, that ideas of the same kind find an echo on this side of the

Channel, and that we are unanimously anxious that his wishes may be realized, and so soon as possible. In the absolute dearth of any photographic news in our own midst, I have thought it better to collect the materials for my correspondence on this occasion from an English source. It seems to me only natural for us occasionally to interchange ideas with our *confreres* in your country, and they will also, no doubt, be glad to hear what is thought in France of their work and of their views, for, humble as my position is, I am not the less a part of the whole which is called France. LEON VIDAL.

ART AND PHOTOGRAPHY.

BY AN ART STUDENT.

WHEN we can fully comprehend the meaning of the word "art," there will be then, and not till then, some faint hopes of mastering the difficulties which are entailed in the production of a picture, either figure or landscape. Before anything can be done, we must first know what it is we are going to do. Now the production of a picture includes, if it is an art-production, the knowledge of so many accomplishments (not necessarily rules), that, to surmount them (a feat which but few men accomplish) takes many years of toil—years of a man's life during which his income is but small, for no true artist with a love for his profession (and he who has no love for it is no artist at all) will turn out work which contains one spot which may offend his eye.

Photographers are saved the necessity of acquiring the rules and practice of drawing and modelling, and here it is that the first cause of their failure is to be found—the fact that they are unacquainted with the forms they wish to portray; for it is only by a close and persistent study of the antique and living model that the artist is enabled to detect the faults and beauties of his own sitter, so as to sink the blemishes by means of light and pose, and bring forth the beauties in all their due importance. Photographers wish to vie with artists, and claim for their work the title of "fine art"; if so, they must follow the beaten track that those who aspire to art have to follow, and win by patient industry in the life schools the power of discerning what is grand, and casting aside as useless that which is petty. The man who bears the proud title of Royal Academician after his name is one (or ought to be one) who concentrates upon a canvas the knowledge of a lifetime, not gleaned by himself alone, but by a study of the works of those who have gone before, coupled with the brain which the Almighty has bestowed upon him, and produces a picture which deserves the name of an art-production in the full sense of the word.

It will easily be seen, then, that the power of producing a grand picture is only to be acquired by years of properly directed study. This point being granted, it is not difficult to understand the reason why so few photographers rise above the mediocre; and it will be so in all time coming, unless they are inclined to devote more time to that portion or branch of the profession which has for its end the making of a work of art. It is to the rising generation that we must look to ennoble photography. The love of gain must be sunk entirely, and the love of the beautiful nursed in their hearts, until they are ripe and ready to enter the field of art, and blossom forth their beauties for our joy and delight.

Having shown, or tried to show, the difficulties—or rather, the work—which lies in the path of an aspirant to fame, we will proceed to consider the meaning of the word *Art*, in so far as it is applied when considering the merits of a picture, and the way in which it is put together; for, according to the powers of the composer, so will the picture be more or less artistic; and if composed in the manner of the general run of photographs to be seen at present, will be reduced to the level of a horror, a blight to the eye, and a mockery to all which is true in nature.

BLISTERING IN ALBUMENIZED PAPERS.

WE have often expressed the conviction that blisters were chiefly due to imperfect coagulation of the albumen; the film in immediate contact with the paper, remaining soluble, becomes detached in the hypo fixing bath, whilst the coagulated outer film rises in blisters, and leaves the paper. In the following remarks by the Editor of *Anthony's Bulletin* this view is confirmed. He says:—

“From all quarters we hear complaints of the working of albumenized papers. These complaints are of two kinds—one as to blisters, the other as to mottling or the appearance of imperfect silvering. These complaints are prevalent in Germany, and are the subject of comment and suggestion by Dr. Vogel in his correspondence; they reappear in the English journals, and in this country are rife.

“Some months ago the Dresden Company sent instructions for the prevention of blistering. As this consisted in soaking the prints after being toned in a weak solution of muriatic acid, parties were undoubtedly a little skittish about using such a method, and incurring the risk of placing the paper while acid in a solution of hyposulphite. The evident purpose of this use of muriatic acid is to thoroughly coagulate the albumen, and thus prevent its becoming softened and soluble to a certain extent (as it undoubtedly does) in the ordinary hyposulphite fixing bath. We use the words, ‘as it undoubtedly does,’ advisedly, on the strength of experiments often repeated, which to us are conclusive. It has for years been our opinion that the albumen spread upon the paper was not thoroughly coagulated by the silver bath. In the case of single albumenized papers the lack of body and lustre produced by long washing was a certain evidence of waste of albumen. In the case of heavily-albumenized papers, the almost constant occurrence of blisters indicates a lack of cohesion between the paper and albumen, which could readily be accounted for on the same supposition. For the purpose of testing the theory we made the following experiments. A solution of muriatic acid of the strength of 1 ounce to 100 of water was placed in a dish, and a sheet of albumenized paper was floated back down until it assumed a liquid glistening appearance; it was then removed and dried. After being printed, toned, and fixed in the ordinary manner, not a trace of blistering appeared, while, as a strong additional advantage, the pictures are more brilliant, print quick and vigorously, and tone with the greatest ease; and the fact that there had been no waste of material was apparent by the greater solidity and stiffness of the print when dry. The fact that a certain portion of the albumen was only partially coagulated by the action of nitrate of silver upon one surface of the sheet only was definitely ascertained by the following test. A print made in the usual way, upon being removed from the fixing, was rinsed in a small quantity of water, and this water was allowed to stand undisturbed for a day or two. Upon examination, in all cases, a considerable slimy deposit was found at the bottom of the vessel. That this deposit did not proceed from the sizing of the paper is evident from the subsequent experiment. A piece of the same paper was taken and treated in an exactly similar manner, with the exception that it was floated back down upon the solution of muriatic acid. The water in which this print was rinsed, upon standing the same length of time, was found to be perfectly free from a deposit, and there was no blistering of the surface. The necessary conclusion, then, is, that when paper is merely silvered on one side, a portion of the albumen is left in a condition which admits of its being dissolved in a hyposulphite solution of the strength of the ordinary fixing bath, and which, when said solution is diluted, is deposited at the bottom of the vessel. As in such cases there is no apparent change of the surface of the print, it is reasonable to suppose that this substance must be supplied from the

portion of albumen next the paper, thus necessarily destroying perfect contact of the coagulated portion of the coating with the surface of the paper—a condition eminently favourable for the action of the causes producing blisters. What these exact causes are is worthy of future inquiry.

“Having pointed out one mode of preventing blisters, it is hardly necessary to state that any other solution which will coagulate albumen applied in a similar way will produce the same effect. We have tried floating the paper back down on a weak solution of nitrate of silver with the same effect, but care should be taken not to use a solution which would be likely to injuriously affect the toning bath.”

WHY DO SO FEW PHOTOGRAPHERS ACCUMULATE WEALTH?

BY N. H. BUSEY.*

THIS has been a matter of surprise to many, particularly when we take into consideration the facts, that the profits in photography are good, and, until the last few years of depression, the amount of business done by photographers of any prominence has been quite large—in fact, there seem to be very few occupations or professions in which, for the same amount of capital invested, as good returns can be realized—and yet, upon looking over the long list of photographers in the United States, we find very few who can be said to be wealthy. While there are, no doubt, in special cases, reasons that are peculiar to those cases, yet in the large majority of instances the influence of certain causes can be so distinctly traced as to justify the application of the term *general laws* to those causes.

The term business, as applied to commercial pursuits in general, is hardly applicable to photography, as photography is really more of a profession than a business; the photographer selling his skill, taste, and knowledge, simply using the materials of which a picture is composed to make his ideas tangible. The merchant buying articles having a market value, and selling them for more than he pays for them, reaps an amount of profit corresponding to the quantity of goods sold; consequently, the more money he invests in the purchase of goods, the greater income he will realize; thus, while he may commence business in a very modest way, yet by the constant application of a portion of the profits of each year, to the capital employed in his business, he in time finds himself in possession of an extensive business and large means.

Unfortunately, this is not the case in photography; any amount of money added to the capital in business beyond what is required to fit up the establishment with the necessary facilities for the production of first-class work, and in a style to meet the requirements of the patrons, is absolutely lost. This condition of things necessitates the seeking of channels of investment outside of the photographic business; and as money judiciously used in legitimate business produces larger returns than can possibly be realized from any other investment, the photographer is cut off from one of the safest and surest roads to wealth. It is a well-known fact, that the safest investments pay the smallest dividends, and in proportion as the gains promised are large, the risk is great.

The natural desire to become rapidly rich prompts many persons to embark in enterprises promising large returns, but which, in most instances, not only do not meet the expectations of the stock-holders, but result in the total loss of the money risked.

A want of judgment in the expenditure of money on the gallery, and of economy in the conducting of the business, are rocks upon which many photographers split.

It has been pretty well proven that large and expensive galleries do not pay the interest on the capital invested

the expense of running an extensive concern amounting to more than a business limited as photography is can bear. Those habits of economy and close watchfulness of expense that are so thoroughly inculcated in a mercantile life, are totally wanting in the education of a photographer.

It is not the magnificence of a studio that gives reputation and patronage to the artist, but the quality of his work. It is a positive throwing away of money, to expend more upon the fitting up of a gallery than is required to furnish it with neatness and good taste, providing the show-room with what is required to show the work of the establishment to the best advantage, and supplying all the necessary facilities for making good work, to the several departments.

Competition being strong, there exists a feverish anxiety in the breast of each photographer to excel his neighbour—a desire to buy this new instrument, that process, to make alterations in his light or in his gallery, or to do something that will draw trade from the place of his opposition to his own.

Photography is advancing with such rapid strides as to cause its votaries to be continually on the lookout to avoid being left behind; this is the reason that photographers are so easily duped by process mongers, &c.

The photographic business is more or less fluctuating, either on account of the deterioration of the work of a gallery, or the natural desire of mankind for a change; it is, therefore, necessary for the photographer to keep his business and private expenses well within his income, in order to be ready to meet a temporary falling off in trade.

A frequent cause of inconvenience and loss to photographers is the unwillingness of owners of property to make the necessary alterations to fit their buildings for use as galleries, not only causing the photographer to withdraw a portion of the capital that he needs to conduct his business, but demanding a higher rent than could possibly be obtained were the premises used for any other business.

It has been remarked that one of the great causes of extravagance among Americans is the cultivation of tastes that are beyond the means of the possessor to gratify. This is eminently so with photographers. The cultivating influence of their profession, and their contact with patrons possessed of wealth and taste, naturally inspires them with the desire to surround themselves with those comforts and luxuries so essential to the happiness of refined and æsthetic natures, not to speak of that ignoble anxiety to excel in show and fashionable style; commanding for the time being incomes sufficient to gratify those desires, and forgetting that there is no guarantee of the continuance of present prosperity, they acquire habits of extravagance and lavishness in their personal expenses, and while they may not spend more than their incomes, yet they accumulate nothing.

A farm seems to be a species of investment that has peculiar attractions for the photographer. Although it is easy to understand how the business man, wearied by the rush and turmoil of a city, should look longingly at the quiet of a country life, and the independence of agricultural pursuits, yet how very seldom has such an investment proven profitable; rather the reverse, as, after spending money, year after year, on improvements, fertilizers, &c., the property sells for less than its first cost. For a city man to own a farm, simply means that he has established a sinking fund, in which to deposit his surplus means, without any return.

After summing up the various causes mentioned in this article, the most important, and the one that probably exceeds all of the others in its effects, is personal extravagance; the spending of the yearly profits as if they were only the income from capital invested, instead of being really portions of that capital; living in fine houses in

fashionable localities, driving fast horses, travelling, and all of those habits that can only be indulged in by the rich. And yet it is gratifying to know that photography is steadily growing to be a regular business, requiring capital, skill, and business knowledge.

Photographers are now rated in Commercial Registers, and are looked upon in the same light as men of other professions and occupations. The amount of capital invested in photography is larger than ever before, and the amount of business increasing from year to year, giving good grounds for the hope that ere many years have passed, the number of wealthy photographers will be considerably increased.

EARNEST WORKERS.

BY L. W. SEAVEY.*

PHOTOGRAPHY has need of more earnest, careful, intelligent, and conscientious workers. There are among its shining lights, working in its varied departments, men whose whole lives are given over to it; to its advancement not only scientifically and artistically, but to help the noble endeavor of placing among the high and honorable callings of this world. Men there are who are working for the pleasure which they derive in the gratification of their tastes and their noble ambitions. Occasionally comes the pang of disappointment at failure, or at non-appreciated artistic results. The close relations between the photographer and his sitters almost daily tax his patience, causing him, perhaps for a moment, to regret being engaged in the profession and practice of photography; but as he recovers his equanimity, he takes fresh courage to try for the higher walks which he knows are still above him.

How discouraging must it be to the earnest workers who produce their results at an incessant expenditure of vital force, and frequently of no inconsiderable sums of money, to find themselves surrounded sometimes on all sides by hordes of wayside robbers, who lay in wait to filch from them their thoughts and visible substance.

By many, how slightly are regarded the sacred rights of property! A new camera-box of superior workmanship is exhibited, and not only at home, but abroad, is it cheapened by carelessly made imitations. A new style of velvet frame is designed, time and money expended, and the imitator lies ready with cheap materials to cheapen a good article.

Cheap camera-tubes, like bogus pianos, bear false inscription. Photographs by earnest, able men are remounted and exhibited as "specimens of our work," or "this style 82.00 per dozen." A leading man of taste procures a background or accessory, and his neighbour immediately gets a poor imitation, and makes and gives publicity to pictures of notorious or disreputable characters to damn the work of the former. No sooner does B. introduce to his customers a new card mount of his own design, than C and D. follow suit, blaming themselves if they do not immediately appropriate B's ideas. And on and on it runs.

And where does all this filching and following lead us to? Are not the upper men crowded upward, and do not the hangers-on drop off slowly, one by one? Are there not fewer persons in the photographic profession now than fifteen years ago? Are there not more galleries of the first class in our cities than formerly, and is not the gap wider between the high and low ones? Is not eternal vigilance the price of the photographer's liberty, artistic and financial? Are not many of our stockdealers making a mistake in continually crying about the ignorance of the photographer; that he does not know a good or artistic thing from the reverse; that price alone is the important item? And is not the photographer who delights in palming off badly lighted, printed, and mounted work, gradually seeing that the public are no longer the stupid dunces he has been considering them?

Will not one frame of striking, new, artistic photographs placed on exhibition in a town of fifteen or twenty thousand so influence or educate the people that they will want the same or similar? And this naturally leads to the question of a teacher. We have, in America, a few leaders in photography who set the fashion for the whole country. They happen to be men mostly who have met with financial success—some with expensive tastes, a part and parcel of, and necessary to, their artistic life. These men excel in their specialties, and in scarcely one do we find the merits of several combined. Still we have no great and willing teacher. Relying on our photographic publications, should we not have something more concise and definite than anything yet published? Who will write and illustrate a book which will not only explain why a figure should be lighted and posed in a given position, but illustrate it with pen, pencil, and photograph, making the right and wrong both palpable by forcible illustration—a book that will guide a man in the narrow paths of good taste, and by the most direct route? Who, I repeat, will write that book, and what will be his reward? Will the first man or men of the country do it? I fear not. Earnest workers with the brush and camera are seldom given to writing books.

Our earnest workers, American and foreign, are a legion slowly but surely increasing in numbers; to their united energy we trust for the elevation of photography to its place in the scientific and art world.

Correspondence.

PHOTOGRAPHIC SOCIETIES.

SIR,—It has struck me, after reading Mr. Brittlebank's paper, that if every one contributed his views on the matter of photographic societies, their management, &c., when fairly sifted the residue might be made use of to alter and materially improve the existing societies. I am an old member of many societies, and the objections I find to the photographic societies are just these.

The annual subscription gives the members nothing except the presentation print and the option of hearing papers read. This, sir, in my opinion, is the first wrong. The presentation print is not valuable to many; and those who can afford to have it framed have plenty of other pictures to fill up the space on their walls, and, in fact, are, to a certain extent, satiated with photography. The others only live in apartments, and are often moving to other situations and in these cases they only become an inconvenience.

Next the papers. They, as a rule, contain nothing interesting, except in very exceptional cases—being generally the product of persons who try to make their names prominent, or stimulate some discussion to enlighten themselves, especially on matters they don't quite understand; in fact, try to suck the brain of the preserving photographer for their own benefit. No men of any particular standing ever come to the society and say what they find out, by which they make their pictures and their fortunes by business.

Photographic societies are not like geographical societies, astronomical societies, engineering societies, surgical societies, &c.: these are appreciated by the general world; whereas photography, say what you will, is largely mechanical. I admit it requires much artistic taste also, but is very mechanical, after all.

Another great drawback is that about ten people do all the business; they are always holding all the offices, and always reading all the papers, except now and then. One more daring member than the rest manages to sew his way in to get his name in print; he then, perhaps, reads papers on—what? Nothing—childish rubbish, known to every little printer's boy. The old hands laugh at it, and think what fools a set of men must be who

pay a yearly subscription to have the right, and also take the trouble, to attend to hear such twaddle. Now and then something good is given by some persevering amateur who has both time and money at command. But this is very seldom, and it's ten chances to one, when he ventures to do this kindness, the set of know-nothings bounce on him like a flock of vultures, and insist that he is quite wrong; so much so, that I often wonder the person don't begin to think he's in the wrong skin, and that he's really some one else. This cavilling by theoretical drones who neither have the perseverance or ability to work the thing out, but insist everything's wrong because their skulls are so thick they don't exactly see it, deters many from bringing anything new before a society.

One society, the parent one, is quite sufficient, and these offshoot societies in London are a failure. The only way I see of making them lasting is to make the meetings conversational, so that any one can say what he thinks, and does not have to mount a rostrum and hold forth—a thing, perhaps, he has never attempted before in his life, and at the bare thought of which he quails and feels he'd rather not.

Let the subscriptions go towards paying for a yearly picnic; or supply each member with a good book on chemistry, optics, drawing, painting, or any work calculated to amuse and instruct, and which might usefully aid him in his business.

My views may be entirely at variance with others, but still if we all contribute, something like good may be taken from all, and acted upon for the benefit of the photographic profession at large.—I am, sir, yours respectfully,
JAMES SYRUS TULLEY.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

SIR.—As notices of certain meetings headed "South London Photographic Society" have appeared in the photographic papers, I am requested by the Committee to state that all indoor meetings of the said Society cease from June 5th till October 2nd.—Yours, &c.,

H. GARRETT COCKING, Hon. Sec.

High Street, Lee, S.E., June 30th.

TRADE MARKS IN THE COLONIES.

SIR,—It may not be generally known that under recent Acts the registration of Trade Marks may now be effected in our Australian Colonies, New Zealand, Tasmania, the Cape, &c.

In view of the forthcoming Sydney Exhibition, many firms are taking advantage of the Acts referred to, and should any of your readers desire to do so, I shall be happy to afford them every information on the subject.

I may mention that several cases have recently occurred of well-known British brands and labels being largely forged in the Colonies.—I am, sir, your obedient servant,
F. DES VŒUX.

Office for the Protection of Trade Marks, 32, Southampton Buildings, Chancery Lane, W.C.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Association was held on Thursday evening, the 26th ultimo, in the Lecture Room of the Free Library,—Mr. J. H. T. ELLERBECK, Vice-President, in the chair.

The minutes of the preceding meeting were read and confirmed.

The presentation print for 1878 was approved of, being a fine Autotype enlargement, 24 by 18, from a negative of Kirkstall

Abbey, by Mr. W. E. Potter, printed by the Autotype Company.

Mr J. A. Forrest exhibited a drop-shutter, and some views of street scenes taken by its means. The latter had been sent to him by Mr. Weaver, of Runcorn. The pictures were much admired, particularly one in which a man on a bicycle was represented.

Drop-shutters of various constructions were also shown by the Chairman, Mr. H. Wood, and the Rev. H. J. Palmer, which were criticised and examined with much interest.

Mr. W. H. Kirkby exhibited an instantaneous view of the mouth of the River Mersey, with the "City of Berlin" entering the port. Mr. Kirkby also showed some specimens of localiate sensitisation of gelatine negatives by means of a strong alkaline pyrogallol solution, applied to the dry negatives by means of a camel's-hair brush.

In a discussion on the necessity, or otherwise, of backing gelatine plates,

Mr. PALMER said he had found that orange paper attached by dextrine answered admirably, at the same time its removal before development was easy.

It was announced that there would be an excursion to Miller's Dale on Saturday, the 5th inst., by the train leaving the Central Station at 9 a.m., the members of the Manchester Photographic Society joining at Marple.

The Secretary was requested to arrange that the July meeting should be an out-door one on the Saturday instead of Thursday. The meeting was shortly afterwards adjourned.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY.

At the meeting on the 2nd of May, Dr. VOGEL in the chair, a letter was read from Herr Reutlinger, drawing attention to the subscription that was being raised for a monument to Niephore Niepce; and the sum of 100 marks in aid of this object was voted by the meeting out of the Society's funds.

Herr SELIGMANN showed a series of transparent photographs received from Herr Talbot, apparently taken by the Woodbury process on transparent gelatine or leather collodion; also a number of double transferred carbon prints by the Autotype Company, of excellent quality. The latter are given partly in a blue, partly in a red, tint.

The PRESIDENT handed round a collection of beautiful American collotypes (called in that country Artotypes), produced by the Obernetter process from negatives by Kurtz and Sarony. He also showed a number of instantaneous pictures of the University Boat Race, sent to him by Messrs. Wratten and Wainwright. Notwithstanding the dull weather which, as the pictures themselves show, must have prevailed when they were taken, they exhibited very sharp images of the moving racing boats and steamers, and elicited loud expressions of praise.

Herr WIGHT reported on the results of his experiments with gelatine dry plates, and exhibited some of those that he had obtained. He had worked, he said, according to the directions of Mr. Bennett, but had found it better to use somewhat less silver, so that the salt of bromine was present in excess. He had dried the plates by artificial heat, and had had occasion to observe that they were reduced by too high a temperature. The emulsion he had kept in a fluid state during different lengths of time, and was able to corroborate the opinion which had been previously expressed, that the sensitiveness increases with the duration of the emulsification. All the plates that he exhibited excited general admiration for the purity and delicacy of the details. Herr Wight added that he had used Nelson's No. 1 gelatine, but hoped also to succeed with German gelatine.

Professor VOGEL recommended the gelatines marked "Extra" and "No. 1" of Lampe and Kauffmann, in Berlin, as being excellently adapted for gelatine emulsion.

Herr FAHLING reported on his trials of Obernetter's gelatine emulsion plates; he found that the emulsion flowed nicely, like collodion, and dried tolerably quickly, but was not as sensitive as he had expected, and could only be intensified with difficulty.

On the other hand, Herr WIGHT expressed a favourable opinion of the sensitiveness of Obernetter's plates.

Herr BERGMANN showed two negatives taken by Herr Lindner, with Obernetter's gelatine emulsion, in about one-third of the time required for a wet plate; they were found to be quite brilliant and intense enough.

The PRESIDENT referred to an interesting paper by Wollaston,

illustrated by sketches of Sir Joshua Reynolds, explaining the fact that a portrait painter or photographer looking straight to the front seems to be regarding the spectator in whatever position he may be placed.

Dr. FRIEDLANDER observed that Brewster had treated the same subject in his "Natural Magic," but had given another explanation of the phenomena.

Talk in the Studio.

SOCIETE IMPERIALE POLYTECHNIQUE DE RUSSIE.—The Photographic Society in St. Petersburg forms a section of the Imperial Polytechnic Society. At a recent meeting, the honour of election to corresponding membership was conferred on Mr. Wharton Simpson, the Editor of this journal, and communicated in terms of the highest courtesy, as a recognition of his services to photography.

BICYCLING PHOTOGRAPH.—Photographers interested in bicycling will be pleased with an instantaneous card photograph of the Hampton Court Bicycle Meet published by Mr. J. Thomas, 28, Tottenham Street, W., for sixpence. The majority of the riders and their machines are well defined; better, indeed, than the mass of lookers-on. The instantaneousity is undecidable, but the light has not been good.

To Correspondents.

AN OPERATOR.—The data you give afford no basis for an accurate calculation of the present strength of the bath. You state its original strength, and the number of plates which have been sensitized in the solution; but this gives but very little indication of the present strength. If you had stated the amount of collodion used, containing a definite amount of iodides and bromides, some idea might have been gained by calculating the amount of silver with which these salts would have combined. But a much simpler mode of ascertaining the strength of the solution consists in precipitating a small measured quantity of the solution by means of a standard solution of chloride of sodium. This will give you the strength with accuracy. Here are the details. Measure carefully with a dropping-bottle, or a minim measure, one hundred drops of the solution into a test tube. Then have ready a 35-grain solution of salt in distilled water, the salt being carefully dried before it is weighed. Now drop carefully the salt solution into the silver solution until no more precipitate is formed. The number of drops of salt solution required to complete the precipitation gives the number of grains of silver to the ounce of bath.

BROMO.—The allusion in the article quoted is somewhat vague; but we presume that the ferrid-cyanide toning solution is meant, which has often been given in our pages and in our YEAR-BOOKS. In this, one drachm of persulphate of uranium is dissolved in ten ounces of water, to which one drachm of ferrid-cyanide of potassium in ten ounces is added. A few drops of a weak solution of chloride of gold are added. The mixed solution is used in a dipping bath gives a warm brown tone. It is generally known as Selle's solutions.

W. W.—There is no objection to using the plan you propose, or to the grooves being made of zinc. Remember, however, that it will be necessary to renew the solution often to secure perfect fixation.

B. Y.—We do not know of any one who undertakes such agency at the present time. If you call upon us by appointment we may be able to give you more detailed information.

OLD HYPO.—It is a great mistake to suppose that greater permanency was secured by the old hypo bath than by the present method of gold toning. It was given up because it was found to be unsatisfactory. See remarks in a short leader.

BENJAMIN MALLOCK.—Copies of the photographs can, we have no doubt, be had of the photographer, who would probably afford the other information required.

ROBERT HAMILTON.—The quickest way of drying a film of bi-chromated gelatine is to subject it to a current of dry warm air. 2. The fullest information on the platinum process of printing can be obtained of the patentee, or the Company working the patent, whose address is 2, St. Mildred's Terrace, Bromley Road, Lee.

S. SNEWIN.—The word Bolton was, by an error of the printer, substituted for Boston. Hence the return of your letter. Several correspondents in our next.

The Photographic News, July 11, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO DR. EDER'S EXPERIMENTS BEARING UPON CARBON AND COLLOTYPE PRINTING—THE INSTABILITY OF TOURIST APPARATUS.

Dr. Eder's Experiments bearing upon Carbon and Collotype Printing.—Dr. Eder's experiments upon the behaviour of gelatine and carbon hydrates in the presence of chromates and under the influence of light should teach photographers something more about the tissue they employ. His researches, as most of us know, have been very exhaustive, for Dr. Eder rarely takes up a subject which he does not earnestly and thoroughly work out. There are, unfortunately, at this moment, but few chemists who make matters photographic their study, the encouragement to do so, we suppose, not being very great. Of Dr. Vogel, Dr. Schulz-Sellac, Dr. Reissig, Dr. Schnauss, M. Merget, M. Poitevin, M. Davaune, Mr. Spiller, Mr. Crookes, and others who formerly did much in photo-chemical investigations, we now-a-days hear seldom, and, for this reason, we welcome more warmly Dr. Eder's valuable results. His researches were not confined to the examination of gelatine in the presence of chromates, but extended to gum and albumen, and, in fact, to most of those organic substances with which photographers have busied themselves in colloid printing, &c. Sugar in admixture with the chromates becomes sensitive to light, although in a less degree than gelatine; it does not thereby become insoluble, however, but only loses its hygroscopic qualities. Gum-arabic and gum tragacanth become insoluble in light if mixed with bichromate, and also lose their hygroscopic qualities. Dextrine, it seems, behaves like sugar, and albumen becomes particularly sensitive if mixed with bichromate. Gelatine forms a coagulated mass with chromic acid, which dissolves on heating. A mixture of gelatine and bichromate, shut off from light, remains unchanged in a dry state for a long time; but a moist mixture, kept at an elevated temperature, becomes, on the other hand, insoluble. The dry mixture is so sensitive that an exposure to light for the fraction of a minute is sufficient to render it insoluble in hot water. Dr. Eder has found that chromic acid under these conditions is in part reduced to chromic oxide, and in this way complications are produced which are not to be ignored. The oxidation product of the gelatine is formic acid, according to Dr. Eder, whose results we need not here further specify, referring such of our readers who desire to study them to that gentleman's original papers. His experiments only go to prove what we have frequently stated, that much more still remains to be discovered in respect to the behaviour of gelatine in the presence of bichromate, before we can regard carbon printing as a perfect art.

The Instability of Tourist Apparatus.—If we are not actually enjoying summer weather, we have arrived at that period of the year when it is usual to look for sunshine and think about one's holiday. Our readers who take a camera with them to wile away their leisure, and seek to bring back with them the scenes that have charmed them—preserving as much of their holiday pleasures as they can for winter use—will be turning their attention once more to travelling apparatus that requires repair or inspection; while those to whom the idea is a novelty will be looking about for suitable camera and stands to accompany them on a pilgrimage. There are many tourist equipments made now-a-days, for we are not referring just now to what a man who means business will take with him, but rather to him who has an eye to pleasuring rather than profit. The principal element in a travelling apparatus of this nature is that it shall be light or portable. Whether it is the rugged hills of North Wales, the placid waters and green meadowland of the Lake District, the wild grandeur of Norway, the rich foliage of Devonshire, or the bright landscapes of France, Italy, or Switzerland, that he determines to depict upon his

dry plates—for he is hardly likely to employ the wet process—the valuable qualities of lightness and portability are sure to be appreciated. If the tourist is unaccompanied, he will be able to carry little personal luggage along with camera, stand, and plate-box; but spread over a party of two or three, a small bellows camera and its belongings are not a serious addition. With the Warnerke roller slide the weight is still further reduced; and those who have some little experience of the flexible tissue will find this dark slide particularly convenient. Only Mr. Warnerke's tissue is not, of course, as sensitive as a gelatine plate. But lightness of equipment may, after all, be paid for too dearly, and this brings us to point out in what way some of the tourist paraphernalia that are made are decidedly wanting. A zephyr apparatus is all very well—the skeleton tripod, delicately-constructed camera, and tiny lens—but supposing them to be both of the most highly-finished workmanship, they lack one great essential—they are not sufficiently firm and stable when set up. The slightest breeze shakes the whole structure; and as small photographs are nothing if not sharp, the result is often worthless. For lantern transparencies, or for enlargements, for which purpose amateurs especially desire their work, unsharp pictures are unsuitable; and although one can tolerate objects being a bit out of focus, you cannot brook blurring, which is the result of vibration. Amateurs very often wonder why their photographs do not make good enlargements, and in nine cases out of ten it is because the pictures are not sufficiently sharp for the purpose. All care in focussing is thrown away if the gossamer apparatus on its frail tripod shakes like an aspen leaf. What, then, is desired is some wire and screw arrangement, or similar scheme, to render the tourist apparatus as stable as possible. Most photographers, after they have been out a few times, have a method of their own; and a ready one is to have recourse to any big, flat stone that may be handy, to weight the camera after the plate has been put in. Another is to employ, where possible, a wall or post or stone in lieu of the camera stand, and thus to ensure a steady pedestal. The great drawback to this *modus operandi* is that one cannot alter the height of the stand nor the aspect of the foreground, as can readily be done with a movable tripod. But it is nevertheless a contingency to bear in mind, and it is well to have one's camera so constructed that it can be focussed and manipulated upon a flat base of this kind, which is not often the case. At the same time, we think that when the tripod is employed, there might be some simple method devised—by tension of wires, &c.—to render the fragile structure as stable as possible. Of course the photographer has it always under his control to open and shut the camera during a blow or a breeze, and he may take his pictures very well at twice or three times, if he so desire; but all this means a certain amount of risk. He may, too, with a little care, shelter his small camera with an umbrella or his own self; but all said and done, the wind will blow the plate to and fro in anything like an exposed situation. The more solid the tripod, the more unlikely is the apparatus to move; but tourist photographers, if they happen to be pedestrians, need not themselves to carry an ounce more than is necessary. The gelatine plate will, in some way, lessen the evil by shortening exposures, and the tourist will find this an alleviation of the evil; but what he wants is more stable apparatus which shall be perfectly portable.

FRENCH CORRESPONDENCE.

MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE—
GELATINO-BROMIDE EMULSION PROCESSES—EMULSION OF
GELATINE WITH BARYTA—NEW TIPPING BATH—TESTING
ALCOHOL—ENAMELLED PICTURES ON A DULL GROUND—
NEW PHOTOGRAPHIC JOURNAL.

Meeting of the Photographic Society of France.—The approach of summer invites to the pleasures of a country

ife all those who are able to allow themselves that enjoyment. Both the philosopher and the operator are as greedy of their holidays as the school boy, who is now also eagerly looking forward to the moment that brings him his annual freedom from books and tasks. Every year, as masters well know, a time arrives when the interest of the scholar in his studies visibly declines, when the excitement of counting the hours that intervene between the present time and that of his liberty obviously distracts his attention. A similar preoccupation and restlessness is, no doubt, the cause why the transactions of our learned societies are from day to day decreasing in interest; there is a general feeling that the time for packing the travelling bag is at hand. This is certainly the reason why the agenda paper of the last meeting of the Photographic Society of France, held on the 4th inst., contained comparatively very little of importance. Of official announcements from the chair there were only two: one relating to the forthcoming exhibition at Montpellier; the other to the exhibition of art and science applied to industry, which is to be opened on the 24th of the present month, and will remain open until the end of December. This latter exhibition will be held at the Palais de l'Industrie in Paris, and will contain a special section devoted to photography.

Gelatino-Bromide Emulsion Processes.—On the resume of the principal articles in the foreign photographic journals being presented to the meeting, it was generally remarked how large a share of public notice is attracted to the great question of the processes with emulsions of bromide of silver in gelatine. M. Chardon pointed out, as regards this subject, that the importance, or rather the necessity, of properly selecting the gelatine to be used in the process could not sufficiently be insisted on. According to M. Chardon, the general opinion appears to be, that no value attaches to the quality of the gelatine, and yet a good gelatine is often the cause of a successful result. Such a remark, from the lips of a man whose whole time is devoted to the study of this popular process, deserves the greatest attention. Generally speaking, the conclusion arrived at, as a result of the discussion of the emulsion processes which so often arises at the meetings of our photographic societies, is that a reliable manual for the guidance of those who work the processes is greatly wanted. The various formulæ differ very considerably from each other, and no one knows which one to employ preferably. Those who work with the same formula often obtain diametrically opposite results. A success which, in another instance, with precisely the same method of operating, is a failure, ought not to be so often recorded. In fact, photography should not be capable of affording material for the reconstruction of the Tower of Babel. It is a question of being able to speak the same tongue to render oneself intelligible. The publication of a sound and standard handbook to the gelatino-bromide process is loudly called for in France as well as in other countries. If, some co-ordination of the various methods be not soon successfully attempted, the exceptional favour with which the process is regarded will soon be put an end to; it will die out like a bright fire of straw. It would seem highly advisable to put this general wish on record, in order that some technical and capable operator may respond to it.

Emulsion of Gelatine with Baryta.—Among the papers read at the same meeting, it may be right to draw attention to a note by M. Chardon, describing a method of emulsifying gelatine with baryta so as to obtain a substance resembling roughened glass. On this one of the members present exclaimed that more than eleven years ago he had produced imitations of roughened glass by means of barium sulphate, and he declared that at the time he had publicly exhibited specimens of his manufacture. This shows, perhaps, that processes which are really good often take a long time in coming into use,

and that at the present day, especially, no one must be in a hurry to claim for himself a new discovery. Better, however, is a re-discovery than that the process should be forgotten altogether.

A New Tipping-Bath.—M. Gobert exhibited to the meeting a tipping-bath of his own invention, which will be of great service, as by means of it development can be protracted for so long a time as may seem desirable. This is another trump card for the gelatino-bromide process, one of whose essential conditions is a slow and regular development.

Testing Alcohol.—At the same meeting M. Bardy exhibited one of Savalle's diaphanometers, an instrument which, though largely used in the wine and spirit trade for determining the commercial value of alcohol, seems not to be sufficiently known among photographers. *Apropos* of this apparatus, a discussion arose on another point which is not wanting in importance. This point is, that operators are not in the habit of submitting to test the alcohols that they employ in their work. And yet the testing is a very simple operation; according to M. Bardy, it is merely necessary to heat a measure of alcohol with its own volume of sulphuric acid to a temperature of 66° C. If the mixture discolours in boiling, the alcohol is unfit for photographic purposes. It must not be forgotten, added this able chemist, that the inferior quality of the alcohol used in some processes is often the source of a failure which is generally attributed to some other cause. For this reason a photographer should never employ an alcohol, though it may have been obtained from the first distillery in the world, without submitting it to a test, which is as reliable as it is easy.

Enamelled Pictures on a Dull Ground.—A very simple means for obtaining on a glass plate, prepared for the purpose, the image alone in enamel on a mat ground, was described by M. Leon Vidal. It is only necessary to roughen the glass all round the oval or rectangular space reserved for the image, by rubbing it for about half-an-hour with emery powder.

A New Photographic Journal.—After mentioning the presentation of the results of their investigations by Professor Stabbing, Dr. Colin, and Messrs. Braun, Ziegler, Balaguy, and Sauvager, I shall have given a full account of the transactions of the meeting, with the exception, perhaps, of the exhibition by several manufacturers of some samples of their most recent work. Talking of manufacturers, it may not be without interest to mention the appearance of a new photographic journal, initiated by Messrs. Guilleminot and Co., published fortnightly by the same firm, and issued gratuitously to their customers. This journal bears the name of *Petite Gazette de la Photographie et des Arts qui s'y rattachent*; its object may be gathered from the following introductory note to its readers in the first number. "The *Petite Gazette de la Photographie* will contain neither leading articles nor advertisements. We are anxious that by means of it all which ought to be known in the domain of photography should be known. Everything worthy of notice will be recorded in it without distinction of country, without respect to person. If by any chance the special organs of our art should fail to draw attention to some valuable discovery, we shall be only too glad to fill up the blank; it will be only necessary to inform us of it. Our columns will be hospitably open to all comers who can render us information. Photographers are invited to give us intelligence of their methods and their improvements; inventors may use the *Petite Gazette de la Photographie* as an advertising agent. There is nothing to pay—not even on leaving; we offer to the public a free channel of communication. Should a photographer in the north want to know something which occurs in the south, our *Petite Gazette* will make his wants known. If any one be anxious to make a general appeal or to ask some special question, our gratuitous post office is open to him; it will be the fault of the correspondent to whom he addresses himself if he does not

receive an answer by return. In short, we wish to make of our little paper a regular medium for gossip, not in the fashion of scandalmongers who talk sometimes for the sake of talking, and always to promulgate some untruth, but as a useful and serviceable means for the interchange of ideas, promptly and openly as in the case of the telegraph. We hope to be ourselves like photographers taking advantage of the action of light, which catches and registers the image, leaving the rest to development, and which conceals nothing, not even the defects." A publication with such a programme will not only be a source of profit to the house which so liberally bears the expenses, but also is likely to render important services in aid of the general interests of photography. K. VERSNAEYEN.

PRACTICAL METHOD OF WORKING GELATINO-BROMIDE PLATES FOR THE STUDIO.

BY A. J. JARMAN.

As enquiries are constantly made about the gelatino-bromide process, as to how plates can be prepared at home, I will venture to give a method that is sure, and, at the same time, easy to manage in the hands of any one possessing a small amount of knowledge in photographic manipulation.

First procure a new tin saucepan, with a close-fitting lid, to hold not less than one gallon of water, and inside the saucepan, on the bottom, solder a piece of tin in the shape of a cross edgewise, so that on it can stand a common earthenware salt jar; around this jar put some water, and also in the jar. Place this upon a three-legged iron stand, and heat it carefully with a jet of gas from a common burner, not a gas-stove or Bunsen burner, as these give too much heat. The temperature of the water must be raised to about 90° or 100° Fah., but must never exceed 100°. Now procure a common pyrogallic acid one-ounce bottle, clean it out thoroughly, and wash the cork well; take a piece of linen about four inches square, and place the cork in the centre, bring the ends of the linen over the top of the cork, and tie them tightly around the cork with a piece of string. This will enable you to pull the cork out easily, as the gelatine is apt to hold rather tightly. Now take of Nelson's No. 1 or No. 2 gelatine, 210 grains; ammonium bromide, 87 grains. Put both of these into the wide-mouthed pyro bottle, and pour upon them 3 ounces of distilled water; put in the cork and shake well. When this has soaked for fifteen minutes, place it in the earthen jar and put the lid of the saucepan on. Keep this all at 90°, which is easily done by placing a gaslight, not larger than the flame of a nightlight, about an inch from the bottom of the saucepan. Put into a glass measure 3 ounces more of distilled water, and 130 grains of nitrate of silver; stir well with a glass rod. When dissolved, pour this into a narrow bottle, cork down, and put in the jar of warm water alongside the gelatine. In the course of half an hour take out the pyro bottle containing the bromized gelatine, and shake it up well; wipe the bottle carefully, and wrap it up in stout brown paper. Fold the paper under the bottom of the bottle, and seal it with sealing-wax, also up the side; leave the top undone. Your silver solution is now of the same temperature as the gelatine. Take both into the dark room, and pour the silver nitrate solution into the bromized gelatine; put in the cork, and shake vigorously for a few minutes. Twist up the brown paper all over the top of the bottle, cork and all, and place it in the jar; put on the lid, and keep at the before mentioned temperature for four or five days, shaking well twice a day. Bear in mind it must be kept warm all night as well as all day, and if very great sensitiveness is desired keep it warm for seven or eight days.

The above method of digesting of course belongs to Mr. Bennett, and thanks are due to that gentleman for publishing such an admirable discovery. The formula given

contains more silver bromide than Mr. Bennett's, although his is an admirable formula when carefully worked.

All being ready now, we take the bottle of emulsion into the dark room, and pour its contents into a porcelain pan of about 8½ by 6½ inches capacity, and allow it to set, of course carefully covered up from all actinic light. During the present damp, warm weather, I have been obliged to place the emulsion, after it has cooled and still in the pan, on some pieces of ice, so as to get it thoroughly set. This done, the emulsion is cut into pieces, and placed in a piece of canvas of the coarsest description, employed by ladies for Berlin wool work. The four corners of the canvas are brought together, twisted up tightly, and carefully, but quickly, drawn through the left hand, and the emulsion that oozes through the canvas allowed to drop into an oblong box, the bottom of which is made of four thicknesses of muslin tacked on. Scrape the emulsion off the hands with a bone knife, and also the remainder of the canvas; put all into the box, and pour water from the tap upon the emulsion, and shake it well while the water is running. This must continue for five minutes; then allow it to stand and drain. This done, pour one pint of distilled water over the emulsion, and let it drain again for half an hour. This done, scrape it from the box into a small milk jug; place the jug in warm water, and add half an ounce of pure alcohol; stir well with a bone knife, and filter into a four-ounce glass measure through a piece of damped muslin doubled into four (say three ounces are filtered). Leave the remainder in the jug to keep warm.

Take a sheet of 32 oz. glass, 3 feet by 1 foot 6 inches, and level it by means of a spirit level and window wedge upon a bench or table; it must be perfectly level, or the gelatine will run all to one end. Suppose three dozen quarter plates are cleaned, take one in the left hand and coat it from the glass measure just like collodion, but do not pour all the emulsion off the plate, for if you do, thin, blurred negatives will be the result. Enough emulsion must be left upon the plate to give it quite an opaque appearance; place it upon the levelled glass, and let it set; continue in the same way until the levelled glass is covered, and, when set, put into a drying box to dry. When dry, take one and expose it for a full-length picture (say two or three seconds at the most), and develop with the following:—

Freshly-made pyro solution
Distilled water 2 ounces
Pyrogallic acid 5 grains

Have ready, mixed in a bottle, the following:—

Liq. ammonia, fort. 880 ½ fluid ounce.
Distilled water 1 "
Bromide of potassium 60 grs.
Bromide of ammonium 30 "

Take 15 minims of this, and let stand ready in a minim measure. Put to your pyro solution one drachm of methylated spirit; place the plate to be developed in a small porcelain pan, and pour on the pyro solution. Keep the pan in motion. Put the 15 minims of ammonia into the measure that held the pyro, and pour from the pan the pyro, and instantly return all over the plate; in from six to twelve seconds a most beautiful negative is the result—in fact, all that one could wish for. Wash off the developer with four ounces of water containing two drachms of methylated spirit, and fix in the following:—

Hyposulphite of soda 10 ounces
Water 20 "
Methylated spirit 2 "

When fixed thoroughly, wash off the hypo. with a little of the spirit and water used to wash off the pyro. Place the plate in a pan, and cover it with—

Water 10 ounces
Spirit methylated ½ (or 1) ounce

allow it to soak in this for about five minutes, rocking

the dish occasionally. Take out the plate, and drain; then, from an ounce measure, pour on to the plate half an-ounce of methylated spirit, pour this on and off for about one minute; stand the plate on its edge on clean blotting-paper, and in ten minutes it is perfectly dry and fit to varnish.

Now, I have found the use of methylated spirit in all the solutions a perfect preventive of frilling. Plates that frill with water alone will not do so anyhow when methylated spirit is employed. This piece of experience I have obtained after using in experiments upwards of one hundred dozen plates.

Now we come to an important part of the gelatine process, i.e., how to intensify a weak negative. With me the following is perfection:—

Pyrogallie acid	60 grains
Citric acid... ..	80 „
Distilled water	12 ounces

For a quarter-plate, two drachms of the above and two drops of strong nitric acid to six drops of the silver nitrate solution twenty-five grains to the ounce of water. Let the negative dry first, then moisten it in a pan of clean water; take it out, and immediately pour on the intensifying solution. The dark-room door must be closed. The weak negative will gradually gain in strength, until perfect printing density is obtained, when it may be washed with water, and dried.

With plates prepared with the formula given here, or with Mr. Bennett's formula, I have never known this intensifier to fail.

I sincerely hope that what I have here written will be of great service to those seeking accurate practical information, as it has been gained by a large amount of experience extending over six months.

PHOTOGRAPHY IN HOT WEATHER.*

AMONGST the various pursuits that may be regarded as "up-hill work," photography in hot weather may certainly take its place. Not only are the incumbences doubly heavy, the dark room or out-door tent doubly stifling, but, worse than all, the chemicals, like spoilt children, are doubly troublesome, and just at the time, too, when you wish them to be on their best behaviour. Of course, one philosophises and invokes patience—prepares a plate with infinite care—in short, does everything most scrupulously clean, only to find a foggy landscape, or a sitter's face the exact counterpart of mottled soap, as results. Such, at least, are the statements that reach us from several of our subscribers, who appear to have exhausted all known remedies, and tired out the patience of photographic friends by their clamorous demands for help. One writer remarks that he has converted a friend into a bitter enemy by his unsuccessful attempts to procure aid, for the said friend, as a photographer, of whom it has been the custom to remark, when any unusually stubborn difficulty arises, "Oh! ask A. about it; he'll be sure to get you out of it!" But lo! even he has no remedy for hot weather. Hence it arises that we are now the recipient of this tale of trouble, not so much in the hope of our being able to administer relief, as to afford at least our sympathy.

We have, however, really so many complaints on the same subject—difficulties from temperature—that instead of replying in our answers in "Bureau of Information" to halt the letters of the alphabet, we propose to discuss the matter here for general reference.

It must be borne in mind that, as a rule, chemical action is exalted in proportion to the temperature, while in some cases, re-actions of a very energetic character become totally arrested as temperature becomes reduced. We may add, by way of illustration, the phenomena of fermentation and decomposition. Is it, then, surprising that the operations, necessarily of a delicate nature, upon which photography is

altogether dependent, should, in like manner, be subject to derangement?

The various ingredients employed by the photographer are each intended to play a special and definite part under certain conditions, one force being restrained by another until such time as it is possible for it to perform effectively under those conditions. If, then, the condition be altered (in our case a given range of temperature), the balance of power becomes disturbed, and we have nought but trouble and confusion instead of harmony and order.

Let us consider now what are our difficulties. First, fogging of the plate in warm weather, whilst in temperate weather the same bath and chemicals yield satisfactory pictures. Now, suppose the bath to be neutral, or very slightly acid, the fogging generally arises from too small a quantity of acetic or other restraining acid in the developer. We call these vegetable acids restraining acids, when thus applied, because when present in sufficient quantities they restrain the reducing action of the developing agent (probably by supplying oxygen) for a certain moderate amount of time, excepting where, under the influence of light, an amount of actinic force has been acquired sufficient to overcome this restrictive action, the amount varying with the temperature. When acetic acid is employed, which is a volatile substance, if the developing solution happen to have been mixed for some little time, in warm weather, it soon parts with a portion by vaporisation. In any case, however, the quantity of restraining acid required is always more in hot than in cool weather.

Some photographers attempt to make a compensation by extra acidity of the nitrate bath, and certainly this proceeding will to some extent remedy the evil; but it is one that we can scarcely approve, because, although the requisite force is supplied, it is not brought into play at the best moment, previously to which time it is positively injurious. Nitric acid is most effective in removing fogginess, but, unfortunately, it also produces materially impaired usefulness for the reception of the actinic impression. Moreover, the nitrate bath then requires restoration to its neutral condition on a return of ordinary temperature. We are strongly of opinion that it is highly desirable to keep the nitrate of silver in as uniform condition as possible. It cannot be denied, however, that under a very high temperature it is almost impossible to secure clear plates without the presence of a very minute quantity of free nitric acid, and when this is the case, we much prefer to introduce it by means of a little free iodine in the collodion, which gives it just where we want it, and in manageable quantities when we require.

The sum of our argument, then, is as follows: In hot weather double the quantity of acetic or citric acid in your developing agent, and if you still get foggy negatives, add a drop or two of weak solution of iodine in alcohol to your collodion, enough to tinge it of a pale yellow colour.

We now come to our second annoyance—a mottled appearance of the plates when removed from the sensitising bath. This we believe to be due to the unequal evaporation of the ether and alcohol from the collodion before immersion of the plate in the nitrate bath. We have frequently experienced this inconvenience personally, but have invariably found a remedy in the addition of a little strong alcohol to the collodion, and allowing a longer time for it to set before immersion of the plates in the bath.

IS PHOTOGRAPHY, AFTER ALL, AN ART?

A CORRESPONDENT of our St. Louis contemporary, writing on the art claims of photography, says:—

As far as photography is identified with nature, it is an art; beyond that, it is science. If photography claims the right of being introduced as a competitor with art, it is the operator who must usher it into these sacred halls.

At present portraiture claims the largest share of attention amongst professional operators, and the bulk of them are neither artists by talent, feeling, or education. The very essence of art resides in the poetry of it, and with-

* Practical Photographer.

out imagination there is an end of poetry. We need only visit the different photographic galleries, and we shall soon perceive the defects of art, which, however, lay in the photographer, and not in photography.

As regards portraiture, the living model is seen in ever-shifting positions and ever-varying aspects of light and shade, very few of which, however, it may be, would be suitable for portraiture, notwithstanding that they are all natural.

That a portrait should be what some call natural does not, therefore, by any means imply that it is perfect as a picture. It may be natural that a person should, at some time, smirk, frown, gape, stoop, loll, or stretch himself, but no one would for a moment dream of perpetuating these actions in a portrait. Notwithstanding, I have seen many photographic portraits in positions little better.

Sitters placed in a chair bolt upright, with head, body, and limbs in one line, a hand thrust forward sprawling on each knee, all arranged with such accuracy that, if the figure were cleft down the middle, the halves would weigh the same to a fraction! The expression accompanying this attitude being generally one of the most listless fatuity, or with every muscle on the strain, the eyes glaring, and the features contracted to a most diabolical frown, the idea is conveyed that the sitter is just gathering his energies for a fatal spring upon some victim. Others, again, carefully avoiding these enormities in arranging the sitter, affect positions of unstudied ease and carelessness, in which, however, everything like grace or dignity is alike wanting. The so-called "composing photographic artist," having exhausted all the stock of his ingenuity in discovering new graceful bendings of arms, hands, and fingers, or a new class of charm for a bodily turn, at length turns his attention to a "photographic impression," full of the above-named cardinal blunders, which of course no one but himself calls a picture!

Such photographers must not only give up their favourite notion that they have only to depict nature to succeed, but also that the most perfect photograph is a pleasing picture!

In thus referring to the defects of photographic pictures, I must not be understood to depreciate our marvellous science. I simply insist that operators who call themselves photographic artists ought, above all, to study the laws by which the painter secures the semblance of nature; he ought to learn how to arrange his subject and choose his point of view; how to secure a proper balance of light and shade, and, in short, how to produce a picture instead of a mere diagram; he ought to be educated for art before he steps to the camera, and if untalented, or a man of no refined feeling or poetry, to keep himself employed in some other branch of social life than one which claims the finest taste of imagination, unmeasured talent, extended intelligence, and the most careful artistic education. The most enthusiastic photographer has often felt his failure here, and has acknowledged that a most complete education of art is pre-eminently needed to succeed in procuring a perfect photographic picture. If, however, attitudes of single figures are so difficult to obtain (pictures pleasing to the eye and to the heart), no one will, I presume, deny that composition is the most difficult department of photography; and does it not, therefore, follow, that it should only be practised by those who have a true artistic feeling?

It certainly is not a little surprising that the leading composite photographers seldom or never attempt the composition of a stereogram. Is it, therefore, not the height of absurdity for men who have not the least sentiment or poetry about them to attempt to illustrate artistic studies from life, or compose a picture? If these would-be artists wish to display their cleverness, why not turn their attention to the hundreds of other subjects which might be mechanically done, and leave that department which is acknowledged by all to be the most difficult, for those who can do it?

If we want to arrive at the point to introduce photography as an art, then the operators must, besides having knowledge of chemistry and optics, be men of talent, refined education, artistic feelings, high sentiments—in short, perfect artists.

A METHOD OF WORKING THE GELATINE PROCESS.

BY E. FERRIER.*

The gelatino-bromide process affords an immense advance upon the old dry methods, by reason of the ease of its preparation, its economy, its great sensitiveness, the absence of all danger in the substances required in its formation, and the banishment from the laboratory of three dangerous products—explosive cotton, alcohol, and ether. My son and I have succeeded in working out a method for its preparation which will enable all persons who practise photography to work it with success and certainty. Here are the details of this process in all their naked simplicity. Place in a bottle one ounce of ordinary water; add 150 ounces of white gelatine of the first quality. The gelatine is then dissolved in the hot water bath with four grams of bromide of ammonium, and seven grams of crystallized nitrate of silver are dissolved apart in the necessary quantity of distilled water. This solution is poured into the bromised gelatine, well shaking the bottle, and it is left about an hour in the hot water bath to facilitate the combination of the bromide and nitrate of silver. The emulsion is then poured into a tray or porcelain dish, and it is left to get cold, when it is scraped up in small portions with a silver spoon and placed in a large jar full of ordinary water, which is agitated from time to time, and renewed five or six times in twenty-four hours.

After this space of time the jelly is withdrawn from the water, drained on muslin, and then introduced into a yellow glass bottle and re-dissolved in the water bath when it is desired to coat plates, which is done in the following manner. Commence by warming the plates; afterwards pour upon the middle of the glass sufficient to cover the whole, and with a glass rod or brush spread it all over the surface; then place the plate on a cold marble or plate-glass slab perfectly levelled. When the gelatine is set, the plates can be placed upon a support and kept in a position where the temperature is slightly raised, taking care the obscurity is complete, because the least light will impress them infallibly. The drying occupies twelve hours, or less may suffice, as it depends on the quantity of heat and the circulation of air in the room. When perfectly dry, they ought to keep a very long time; but this trial not having been rigorously made, it is not yet possible to state precisely the duration of their keeping qualities.

This is how the image is developed. Two solutions are made:—

	No. 1.	
Distilled water	100 cub. cents.
Pyrogallic acid	1 grain
	No. 2.	
Water	1,000 cub. cents.
Liquid ammonia	15 "
Bromide of potassium	5 grams.

The film is soaked in ordinary water, then covered with solution No. 1 for one minute; now add an equal quantity of No. 2; and this mixed solution completes the development. If it become strongly coloured before the image is completed the plate must be well washed, and the development continued with a new mixture of the two solutions. It is washed when finished, and fixed with hypo. It sometimes happens that the film of gelatine lifts during development, which is a serious inconvenience. To prevent this, add to the emulsion two or three drops of a 5 per cent. solution of chrome alum.

PHOTOGRAPHS OF SPRING BLOSSOMS.

We have been favoured by Mr. L. Berry, of Chorley, with examples of some excellent photographs he has recently produced of the spring blossoms of flowering shrubs and trees—an application of photography which, as he very rightly remarks, is much too rarely attempted. The examples before us include lilac, horse-chesnut, and hawthorn, each making a charming picture, photographed about half the size of nature upon a ten by eight plate.

Few photographers would believe, until they had made trial, what a pleasing and picturesque effect is produced by a good photograph of a well-selected bough from a flowering shrub. And besides securing pleasing pictures, studies of considerable scientific value from a botanical point of view may be obtained. To secure this, a little prior botanical study would be desirable, so as to understand how best to deal with each subject. A complete series of the blossoms of flowering trees and shrubs indigenous and cultivated in this country would be of great interest and value. But to obtain these, some knowledge of the habitat and season of blossoming would be necessary. For whilst many flower in spring, like the hawthorn, lilac, ribes, chesnut, laburnum, wisteria, &c., there are also many of the shrubs, like varieties of the hibiscus, althea, &c., which blossom in late summer.

If any of our readers be at a loss for something quite fresh at the forthcoming Exhibition, where medals for special excellence in unnamed directions may await them, we commend to their attention such a series as we have indicated. The study would be itself a delightful and an improving exercise, which to many would prove its own reward. No course of exercise would better serve to practise the student in mastering all the ins and outs of technical photography. For the work would need doing well, and would develop in the student a familiarity with all that photography can effect. The pictures must be perfectly modelled and full of gradation, and carefully defined. To secure good definition in all parts, it would be desirable to use a small lens, producing the negatives (say) card size, then carefully enlarging afterwards, as the pictures should not be less than half the size of nature. A little care in grouping and securing effective light and shade would be necessary. Where it could possibly be managed it would be desirable to photograph the blossom as it was found hanging on the tree. But in some cases this would be

difficult, if not impossible. It would then be desirable to secure a good-sized branch, and, if possible, keep it in water from the time it was cut until it was photographed, so that no appearance of wilting or withering may be presented. Bloom just opened and just opening should be selected, as over-blown examples are uninteresting. Sufficient leafage should always accompany the blossom to maintain the character, and in some cases it forms half the beauty of the picture, as in the horse-chesnut, for instance.

At the last one or two Exhibitions no floral photography has been exhibited. We hope to see at the next many fine examples of various phases of this interesting branch.

PREPARING AND WORKING GELATINE EMULSION PLATES.

THE subject of gelatine emulsion has been constantly brought under the attention of photographers for some years, and many papers containing instructions for their preparation and use have appeared. It is only within the last twelvemonth, however, that photographers generally have been brought to a knowledge of the great possibilities which these emulsions possess, and we have of late received repeated enquiries from photographers, who have previously given no attention to the matter, for a clear and succinct statement of the operations. Most of the papers which have recently appeared on the subject have, they complain, been chiefly devoted to modifications and improvements, a knowledge of the general operations being pre-supposed. This is a very natural condition of things. Photographers who read their journals, and occasionally experiment and verify what they read, are *au courant* with the constant progress of their art. But the Rip Van Winkles, who suddenly wake up to find that mighty changes and improvements have been made whilst they slept or gave no heed, have often much leeway to make up when they wish to get the advantage of the mighty wave which is floating others on the tide of success.

As a rule, we can only refer enquirers back to various published articles. We are enabled this week, however, to aid those anxious to work the gelatine emulsion process, and have failed to keep abreast with the times in information, by a very complete statement of all the practical details of the process, stated simply and clearly and plainly by a practical man, who has worked his way through the difficulties to a complete success. We are indebted for this to the courtesy of Mr. Jarman, of Ramsgate, who sends examples of the excellent results obtained in the studio by the process he describes. Mr. Jarman emulates the spirit of the old pioneers of the photographic art, to whose enthusiastic liberality the very existence of the art is due.

At the present moment the bulk of the gelatine plates used are prepared commercially, a system which has all our approval. For it is certain that if the photographer can be fully employed in producing negatives on trustworthy plates he can purchase, it will answer his purpose better to buy than to prepare his own plates. But it is very desirable that he should be able to prepare his own plates, and rely upon them in emergency, when he might possibly be unable to buy a stock upon which he could safely depend. We know one of the best makers who will only send out such plates as are prepared under his personal superintendence, and his customers have at times to wait until a fresh supply can be prepared. Each customer should, under such circumstances, be able himself to prepare for immediate necessities. And the article of a practical man, to which we call attention, will materially aid them, and save the necessity of much back reference.

PHOTOGRAPHIC SOCIETY OF IRELAND.

WE are glad to be able to announce that a Photographic Society for Ireland is once more an accomplished fact, and will, we hope, prove a success. From the programme and rules now before us, we learn that the project will resemble that of other similar societies in this country. The meetings will be held monthly, on the second Wednesday of each month. The first meeting was announced, for the ninth of the present month at the Queen's Institute, when papers on the gelatino bromide process would be read and discussed. The first president of the Society is Dr. Emerson Reynolds, a name well known to photographers. The secretary is Mr. Alexander Conan. The entrance fee is ten shillings, and the annual subscription the same amount. We wish the Society all prosperity, and shall have pleasure in chronicling its proceedings and progress, if the Secretary will kindly communicate such matters as he can for insertion in our pages.

NEW PROCESS OF PHOTOTYPIC.

OUR valued French correspondent, M. Léon Vidal, in his letter which appeared in our last week's issue (page 319) refers our readers to his article published in the *Moniteur de la Photographie* of the 1st June, for a description of the process by which he produces a collotype block ready to be printed with ordinary type. For the benefit of those of our readers to whom our French contemporary is not available, we reproduce here a translation of that portion of the article which gives an account of the new process.

Phototypic is a sort of lithography in which the stone is replaced by a hygroscopic layer of gelatine impressed with an image by the action of light passing through a photographic negative. Now, if we could cut down a lithographic stone both in its surface dimensions and its height, to make it like a wood block, we should be able to insert it in the text, and take an impression from it simultaneously with that from the type. The difficulties in the way of doing this would be, firstly, the necessity of wetting the stone previous to each impression; and, secondly, the expense of cutting down lithographic stones, which would entirely lose their value in the process. But what we are on this account prevented from effecting with natural lithographic stones can be managed with an artificial one, provided that the latter possesses an hygroscopic surface from which, after being saturated with water, numerous impressions can be taken without its being necessary to wet it afresh. It became, therefore, necessary to make photo-printing blocks of the requisite size and height to be set up in the forme with ordinary type, and possessing so great a hygroscopic quality that the moistening requisite to produce an impression should only be an accidental operation, and not one that is indispensable before each pull.

Now the ordinary process of phototypic was scarcely adapted for this purpose without modification. The plates in this process are made of metal, or glass, or even lithographic stone, always larger than the image of which it is required to obtain an impression, and it would be impossible in every case to cut these plates to the size of the printing block. M. Vidal adopted another method for arriving at the same result as that produced by ordinary phototypic. He prepares the artificial lithographic stone and the hygroscopic support separately, and then attaches the one firmly to the other. The image is obtained as in the ordinary carbon process; an impression on carbon tissue is developed on a roughened glass plate coated with some fatty substance. When, by means of hot water, the picture is divested of all the gelatine not acted on by light, it ought to appear with all its half-tones like a good carbon print which is ready to be transferred to its definite support. This is then enclosed in a frame of thick cardboard, bevelled outwards on the inside, and coated entirely with paraffin or wax; the frame is then

filled with the following composition, which is poured into it and over the picture:—

Gelatine	20 grammes
Gum-arabic	20 "
Glycerine	40 "
Water	100 cub. centim.
Ammonia	5 cub. centim.
Alum	0.5 gramme
Salicylic acid	2 grammes
Barium sulphate	10 "

The salicylic acid is added as an antiseptic, and the sulphate of barium gives to the layer of gelatine an opalescent appearance. The whole layer should be so deep as to have, after drying in the chloride of calcium box, a thickness of about five millimetres. When the desiccation is complete, the layer above the glass plate is turned out, and will be found to have the image transferred to it. We have now, therefore, a plate of gelatine bearing on it the picture of the exact dimensions required, and bevelled downwards from the edges, which latter will therefore not take any ink. This plate must then be mounted on a sheet of copper or zinc, which is raised on a wooden support until the height of the image is the same as that of the type with which it is to be printed. The gelatine plate is next saturated with moisture by immersion for a quarter of an hour in a bath composed of—

Glycerine	50 grammes
Water	50 cub. centim.
Alum	2 grammes

and the image will appear on its surface in considerable relief, so as to render it particularly well adapted for printing from. The separation of the black parts of the picture from the white parts of the hygroscopic gelatine is very perfect, so that no smudging, such as so often occurs with printing blocks on which the shadows are modelled by fine lines close together, need be feared. The mixture of which the formula is above given is of so hygroscopic a character that repeated wetting is rarely necessary. It must be effected with a sponge dipped in a mixture of half water and half glycerine, after having removed from the plate all trace of ink; but the latter should never be severely washed.

In this way, then, we obtain a carbon print, but with a light-coloured pigment, so that the degree of inking can be readily determined. Light-coloured earths in the form of impalpable powders, with a gelatine chosen for its resistant properties, make a very good tissue. The print should not be treated with alum before pouring on the layer of hygroscopic gelatine, otherwise it will not transfer easily. On the contrary, it is better to wash it with water containing a little ammonia, which will facilitate the penetration; the mixture already contains some ammonia, and the transfer of the image to the plate of glycerine and gelatine is thus rendered completely effectual. The alum contained in the first liquid used for moistening increases the hardness of the image, and prevents it from swelling too much.

It is easy to imagine what advantages can be derived from a process of this kind, which enables us to produce, at a moderate cost, plates capable of being inserted among type for the printing press. A number of different blocks obtained by this method can be mounted in the same form with the type of the text, and can be pulled all together in the press. They can be used in cylinder presses also, without any difficulty. Until the contrary is demonstrated, M. Vidal believes that this is the only process by which photographic printing blocks capable of being printed simultaneously with type can be produced.

A BIT OF PRINTING EXPERIENCE.

BY W. T. WILKINSON.

IT is some time since I have had any trouble with the printing department, as I was scarcely prepared for a series of troubles met with during the last fortnight.

For my first batch of prints I made up a new silver solution—sixty grains to the ounce made neutral by the addition of carbonate of soda—floated the paper three minutes, and the results in the printing frame gave me no uneasiness; but in the toning bath no other colour could be got but a very cold and slaty blue, very poor and flat, without vigour or richness. My first idea was that the paper I was using required an acid bath, so I added nitric acid to the bath until very slightly acid; but on printing paper sensitized upon it (floating one minute to three or five minutes), the resulting prints were exactly the same as before.

The bath was then made alkaline with ammonia, and the paper floated three minutes with slightly better results. I then set to work and made a fuming box, floated the paper one minute, and fumed ten, and lo! my troubles were ended. I got prints that left nothing to be desired—*except permanence*.

Now this bit of experience has suggested a reply to the query I have often seen in the journals, viz., why was ammonia fuming so extensively practised in America, and so little in England. It also gave me a clue to bad prints in England during the height of summer. In America, as here, the atmosphere is very dry, as it is in England sometimes when the thermometer gets over 90°. Under these conditions there is not sufficient moisture present in the paper to give the requisite vigour during printing, and if the reduction by light is not sufficient, the gold cannot give a vigorous colour, and ammonia fuming supplies its place.

My experiments in Ceylon bear out this view of the case, as I well remember, during the dry winds of the N.E. monsoon, I found a great advantage accruing from ammonia fuming, but did not find any appreciable difference in the prints; when last June (the rains having set in) I was obliged to discontinue its use on account of not having any ammonia in stock.

If, during the present summer, any difficulty is experienced in getting vigorous prints, I venture to predict that fuming the paper before printing will be found an effectual remedy, and as the time of floating can be reduced to one-third, the saving of time will be found to more than counterbalance the cost of ammonia and trouble of fuming.

As the most engrossing theme in the journals just now seems to be dry plates (collodion and gelatine). I may say that I have been working with both processes, and have found them everything that could be desired. On my way up here I used plates prepared with collodion for still life, and gelatine for subjects requiring quick exposures, and although in many cases the exposures given were abnormally short, I got better results than could be got with the wet process; especially under the circumstances then ruling. The only difficulty I have ever had with gelatine was the absolute necessity of having all solutions cold, and also being careful that the negative was dried in a cool place. Perhaps a bit of experience on this point I met with in Ceylon may be instructive.

One day I had brought me six of Wratten and Wainwright's gelatine plates to develop, that had been exposed on board ship; the first negative was all right until washing after fixing, when away the image went down the sink, much to my disgust. Operations were suspended until ice could be put into the tank containing the washing water, when the other five negatives were developed, and washed without accident; and as the owner was going away quickly they were left to dry on a rack upstairs in the studio, just away from the hot part of it. Three stood the treatment all right, but on the other two the film had run slightly, giving the most grotesque image it is possible to imagine, and suggesting that the camera, ship, and the group of passengers had all been very seasick at the time. Of course, in such a climate as Ceylon, collodion emulsion is easier to manage; but, alas! the speed cannot be com-

pared with gelatine, although the ferrous oxalate developer may help collodion up a little; at any rate, now I have got the formula, I mean to give it a trial. In saying I have got the formula, I might explain that the numbers of the journals last year containing it, by some mischance or another, did not reach me, and although I tried to get them again, I could not fill up the gap, and had to wait until just before I left Ceylon.

I am now in the Himalaya at one end of the Hill Stations, and at the end of the summer I go down into the Plains, so if any useful experience crops up I will communicate with you again, as I find the best way of carrying out Capt. Cuttle's motto, "When found make a note of it," is to send the note to the NEWS, and then it can always be found.

PERSPECTIVE FOR PHOTOGRAPHIC STUDENTS.

BY J. MARTIN.

My last paper referred principally to the horizontal line and point of sight. This latter is, with very rare exceptions, always to be found in the picture, otherwise the artist must have stood on one side of it, and looked askant while working. I remember a portrait by Gainsborough of King George III. having this peculiarity. His Majesty is represented as walking forwards, and thus the artist obliges the observer to stand on one side, and leave room for the king to pass on without obstruction. But a landscape thus painted would appear in false perspective. Neither should the point of sight be placed exactly in the centre, as nothing is more ungraceful than repeated lines on each side of the picture, or to see a long street, road, or an avenue placed directly before you. In fact, photography produces so little difference of tint when representing green, brown, and red colours, that the ground would very probably seem to rise like a wall, rather than recede towards the distance. Supposing the horizontal line to be five feet from the base of the picture, then we divide one of its sides, measuring from its base to the horizontal line, into five divisions, we shall have one foot in each; and continuing to make off such divisions up to the top of the picture, we shall thus be able to estimate the height of every object it contains. Supposing for instance, the top of some picture reaches from the base of the picture to the fifth division, inclusive, above the horizontal line, then that object will be ten feet high; supposing this object to be a wall or shelf, &c., a line drawn towards the point of sight from a perpendicular one, marking its height, will give the upper extremity of such objects in perspective; another line drawn from the base of the upright one will give its lower extremity. Of all objects lower than the high we see the upper surface, and of those higher than the high, we see the under surface; thus we are enabled to judge very nearly of their relative height. As a familiar example of this, we may notice the long rows of shelves, bottles, and drawers of a chemist's shop; as their lines recede towards the point of sight, they appear to approach each other, and the shelves, &c., would seem to be shorter and closer at the farther end than they are close to us. But we know, by experience, that this is not the case. This may be termed a natural or instinctive education of the eye.

When photographic lenses are used which cause these lines to converge too rapidly, then a species of distortion is produced which will not allow objects at various distances to be introduced into the same picture, and a group of figures must be placed, like the jolly hutchers, all of a row. Even a single figure sitting sideways will appear to have one side, hand, and foot much larger than the other; and a hat held a little in front will appear in about the proportion of a washing copper. The lines above spoken of and the point of sight are termed by old authors the *vanish-point* and *vanishing lines*.

SOMETHING ABOUT IODINE IN PHOTOGRAPHIC STUDIOS.

BY K. SCHWIER.*

THE use of iodine is as old as picture-making by the agency of light. Nevertheless, it seems to me that it is not fully appreciated, and I would like to draw the attention of our practical photographers to some of its good qualities. There is no better thing known to me, for instance, to free a cuvette or bottle from old silver residues than the solution of iodine in water and iodide of potassium :

Iodide of potassium	10 grammes
Iodine	7½ "
Water	2½ "

Triturate in a mortar until a brown solution is obtained. We will call this iodine water. To remove silver stains, touch them with this solution, and afterwards dissolve the iodide of silver and free iodine by means of hyposulphate of soda or aqua ammonia.

It is also very useful in strengthening or reducing the intensity of negatives, though a yellowish stain of iodine is often left behind.

When diluted with forty times its bulk of water, it is an excellent thing for cleaning silver prints, dishes, and hands from adhering hypo.

In short, iodine water should be missing in no gallery.

Correspondence.

PHOTOGRAPHY AS A BUSINESS.

SIR,—The article in the current NEWS by Mr. N. H. Busey, from the *Photographic Rays of Light*, is very interesting, but I would like to apply a somewhat similar question—and answer—to a much larger class of men than Mr. Busey was thinking of when he wrote the above article.

Your paper is read extensively among small photographers and assistants, and it is of them I am thinking. It is obvious that we cannot all be upon the top rung of the ladder—certainly not at the same time; and, as a matter of fact, there are very few engaged in photography who make so much money at it that they have to look for other means of investing it. I would ask, why do so few photographic businesses pay, and why do we see so many photographers struggling and hard-up during the slack times? And the answer is, that so many who engage in photography as a business expect too much of it. In years gone by, when there was not nearly so much work in or upon the work as there is now, when there were not so many photographers, and prices were higher for inferior work, a man working single-handed, or nearly so, might make more than a living—perhaps buy the house he had been renting, and one or two more; but in these days it is not so. Supply and demand are matters that will always find their own level; if they do not, trade competition will very soon do so for them.

Small businesses will not pay. The tradesman who commences business—no matter what it is; it may be a small draper or a clothier—with a small capital, and only gets enough call to help himself and perhaps one assistant employé, will tell you that he is only making a living out of it—perhaps not that; but if he is industrious and persevering, in the course of time he may keep half-a-dozen assistants employed; then he may make money; and the more assistants he can keep employed, the more money he will make. Reason why—each of his assistants will earn for him, with the assistance of his capital, a little more than he pays him. Please note that it is not the amount of capital that does it only, but the rapidity with which that capital can be turned over.

* St. Louis Practical Photographer.

It is just the same in photography at the present day. Those who love to call it an art may do so, and I shall not want to quarrel with them about it; but it's a trade for all that, and as a trade it must be regarded by all who wish to make money at it, and they must accept the fact that they cannot get twenty shillings for fifteen shillings' worth; or, if they do, they will not do so long.

Small businesses will not pay. The young operator who jumps into business for himself, thinking that he will surely be able to clear his expenses, and that will be better than working for someone else, is in a fair way to learn something. He means to start in a small way, and do all the work himself, with perhaps an apprentice or two, so as to keep the expenses down as low as possible; but he will probably find that they amount up to £2 or £4 a week. This he has to earn before he has a cent. for himself; he has to earn £6 or £7 a week before he is as well off as he was while he was getting fifty shillings a week wages. As there is a great deal of idle time in wet weather, he will find himself very much overworked in fine weather—and fortunate at that; but if he is energetic and persevering, he may soon find himself able to keep a printer; then his times will be a little easier, and better and better as he can increase the number of his assistants—and for precisely the same reason as I mentioned in the case of the linen draper; but he must still work; he must not fall into the too common error of one man thinking that two or three assistants can keep up a large house and himself, and perhaps family, in idleness or partial idleness.

Many employers do their assistants a great injustice in this respect; they work them long hours, and probably express dissatisfaction with them afterwards. I would like to impress upon them that where the work is mixed, two men, by dividing it into departments, will easily do three times as much as one could when he had to run from one thing to another.

We are hardly called upon to recognize those employers who engage an operator and want him to do a little operating, a little retouching, a little printing, and a little something else, and offer him—well, anything over thirty shillings a week. But, unfortunately, there are a great many of them. The best I can say to them is, that the sooner they give up their businesses—yes, my friends, give them up; don't sell them, because you know very well that the buyer would be the principal article sold—and take situations, the better it will be for the parties concerned.

I shall probably, with your consent, have something more to say at a future time about "Photography as a Business."—Yours respectfully,
MASS.

COLOURED MINIATURES ON GLASS.

SIR,—Having seen your article in last week's issue under the above heading, I thought I would address a few lines to you explaining a process that I have been working for the last three years. At about that time an American by the name of Carpenter came round our way and sold my employer (M. Medrington) the right to work this process in Bath. As the whole affair has exploded, there can be no harm in my briefly describing the *modus operandi*, and you will see how nearly we tread upon the patent of Mr. B. T. Irish.

In the first place, we take a rather over-printed picture, tone well, fix as an ordinary print, and wash well; then proceed to mount (face downwards) using a paste composed of two parts starch to one part corn-flour: use a squeegee to ensure complete contact to the glass and to expel any particles of superfluous paste. Care must be taken that the picture, from the moment of printing to the mounting, be kept moist; if allowed to dry, the minute cracks produced in the albumen separate themselves from the glass, and in a very short time give the picture a faded and mildewed appearance.

The mounting having been successfully accomplished, the picture is left to dry, and then plunged into a pan of boiled castor oil, warmed up to within a degree of boiling, and then left the matter of a night to soak. In the morning the picture is taken out, and rubbed clean with a rough cloth, when it will be found to be beautifully transparent, and ready for the backing glass, whereon the colour is put. With vignettes this process answers admirably, giving a softness, and, if the colour is skilfully applied, a richness, that defies description. The colours having been applied (oil colours diluted with turps), the two glasses are then joined together by small slips of gold beaters' skin, enclosed in a brass case backed up with cardboard to fill (the said cases, I believe, were made for the purpose by Messrs. Marion and Co.), and the picture is complete.

At one time I had a lot of tlick Saxe paper, and the prints produced by it could not be rendered so clear or transparent as the fine Rive that I had used previously, and then it was that, cudgelling my brains, I fell upon a happy idea. It certainly was not emery paper; but you will find it, I think, cleaner, and, if you try it, far more certain in its results.

My plan was as follows:—I let the picture dry thoroughly, so that the albumen had a sure hold on the glass, then moistened the back with a sponge and clean water; then, taking a soft piece of india-rubber, I removed almost every trace of paper, leaving a beautifully clear picture. This process can easily be accomplished, as, if the mounting be properly done, the albumen adheres to the surface of the glass so tenaciously that it would require a knife to scrape it off.

I have thus briefly described our process, and I think you will find very little difference between it and what Mr. Irish wishes to get letters patent for; for you see that what I have described is really and truly "a process for preparing and producing coloured photographs on glass (face downwards), then grinding it thin at the back, and then treating it with paraffin, or its equivalent, as specified, or the after-reception of oil colours, applied directly to the back of the picture, or to a second glass to be applied as a backing substantially as herein described."—I am, yours respectfully, GEORGE BRADFORD.

DEVELOPING GELATINE PLATES.

SIR,—I am using a collodio-bromide emulsion and rapid dry plates, and I use the following developer:—

Common washing soda	1 ounce
Bromide of ammonia	75 grains
Strong liquor ammonia	$\frac{1}{4}$ ounce
Water	10 ounces

For half-plates I take about half-an-ounce of the above developer, and after flowing it over the plate a few times, I add pyro acid dry—about the size of a pea—and stir into the developer. With correct exposure I get excellent negatives; but if the plate should get a little over or under-exposed, I fail to get anything like a presentable picture, on account of not knowing the best method of modifying the above developer, the usual bug-bear—fog—making its appearance.

Perhaps you will kindly suggest through the PHOTOGRAPHIC NEWS a method of modifying the above developer to suit a plate either a little over or under-exposed. In most all other alkaline developers one generally sees the alkaline developer modified to suit a plate that should be over or under-exposed. Your kind suggestion would probably save me a lot of trouble and expense experimenting. I thought of making up three developers—strong, medium, and weak.

<i>Strong.</i>			
Bromide ammonia	50 grains
Liquor ammonia	$\frac{1}{4}$ ounce
Soda water	10 ounces

<i>Medium.</i>			
Bromide ammonia	75 grains
Liquor ammonia...	$\frac{1}{4}$ ounce
Soda water	10 ounces
<i>Weak.</i>			
Bromide ammonia	96 grains
Strong liquor ammonia	$\frac{1}{4}$ ounce
Soda water	10 ounces

Commencing with the medium developer, and if found over-exposed, wash off at once, and commence again with the weak; and if under-exposed, wash off, and commence afresh with the strong developer. Would you recommend the above method? Would the light at twelve o'clock at night (this time of the year), passing through a crack in a door, fog a sensitive dry plate?—Yours respectfully,
AN AMATEUR.

[It is probable that the proposed plan may be found of service. Perhaps some of our readers, fully experienced in developing rapid plates, may be able to give our correspondent a hint.—ED.]

INTENSIFYING GELATINE PLATES.

SIR,—Let those who use the alkaline pyro-developer for dry gelatine plates, and wish for more density, use bichloride of mercury, and they will be able to get what amount of density they please; afterwards flood with ammonia, which will alter the colour of the film to much the same as if developed with the oxalate of iron.

The only fault I find with it is that it has the effect of hardening the high lights; this would, I think, be an advantage to those gentlemen who find a want of crispness and brilliancy in the high lights of a fully exposed landscape negative.

I have not tried this intensifier on landscape negatives, as up to the present my experiment with gelatine plates (which, I might mention, are Swan's) has been principally in the studio; but I intend trying what I can do with landscapes with them before the summer is over; in the mean time I should be glad to hear the opinion of a few of the gentlemen who do work gelatine plates on this intensifier.—Yours truly,
W. J. HUNTER.

EXTRA MEETINGS OF SOUTH LONDON MEMBERS.

DEAR SIR,—In answer to the letter from the Secretary of the South London Photographic Society in your last number, I feel called upon to offer some explanations with regard to certain notices which have appeared in the photographic journals respecting the auxiliary meetings which have been held at my studio, 4, Tottenham Court Road.

If you will kindly refer to my letter of June 13, you will find that therein I simply offer my rooms for conversational meetings of the members of the S. L. P. S. during the recess of that Society, the between dates of which were known to all interested or connected with it; and in justice to me, I think you must admit that it was more in consequence of the editorial construction put upon my offer, than any statement of mine, that anyone would be led to suppose the meetings were to be of an official character. I would not have taken that liberty with the Society without first consulting the Managing Committee, and every right thinking man must confess that it would, to say the least of it, be extremely impolitic to allow the credit of the Society to be placed at the call of an individual member.

With all respect, then, to persons and position, the Committee of the South London Photographic Society must please to accept my apologies for any fancied slight or irregularity which I may have committed, and in continuing to throw open my rooms for the use of members of the Society on Wednesday evenings I do so with the sole object of affording my friends and professional brethren the opportunity of meeting each other for conversation and comparing notes on various subjects in connection with our art.

Certain statements have reached me to the effect that I have some commercial or personal object in view. I think I may, however, safely leave the refutation of such calumny in the hands of those gentlemen who have been present, and, in conclusion, say that the success which has attended my humble efforts, and the pleasure I have had in meeting my confrères, more than repay me for the small amount of trouble it has given me.—Your obedient servant,

ARTHUR BRITTLEBANK.

PS.—The meetings will in future be known as *Photographic Conversazioni*.

[If some of the South London members desire to have additional meetings for discussing photography, and Mr. Brittlebank choose to lend his studio for such meetings, we cannot see any legitimate ground of objection on the part of any one. Possibly it was well that it should be understood that such meetings were outside of the Society's sanction or control.—Ed.]

Proceedings of Societies.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of this Society was held on the 1st inst., the Right Hon. The LORD DE ROS in the chair, which was, however, occupied during the latter part of the meeting by the Right Hon. the EARL OF ROSSE.

The minutes of the last meeting having been read and confirmed, the following members were elected:—J. L. Ranking, Esq.; George Brook, Esq., Jun.; F. H. Shaw, Esq.; Alfred Wilcox, Esq.; A. Hunter, Esq., M.D., F.R.S.; Rev. G. P. de Putron; and W. Stewart, Esq.

In consequence of the death of Mr. Sopwith, who had filled the office of referee in conjunction with Mr. Glaisher for many years, Mr. W. H. Howard was elected to fill that office, and Captain J. C. Lewis, M.A., Governor of H.M.'s Prison, Pentonville, was elected a member of the council.

The SECRETARY then laid before the meeting the pictures for the current year, and Mr. GLAISHER then read his report, of which the following is an abstract:—

Class 1 contains 111 pictures, contributed as follows:—R. O. Milne, Esq., 20; W. S. Hobson, Esq., 11; R. Murray, Esq., 9; E. Swinburne, Esq., 9; F. Beasley, Esq., 8; J. W. Leigh, Esq., 8; G. G. B. Creswell, Esq., 7; J. W. Richardson, Esq., 5; T. R. Shervington, Esq., 5; Rev. W. Hancock, 5; T. Brownrigg, Esq., 4; The Marchioness of Anglesey, 3; R. Leventhorpe, Esq., 3; J. L. Ranking, Esq., 2; Captain J. B. C. Fox, 2; Major Chadwick, 2; Rev. H. Palmer, 2; W. Vanner, Esq., 2; W. Armstrong, Esq., 1; W. Muller, Esq., 1; A. Watkins, Esq., 1; and J. H. Ritchie, Esq., 1.

Class 2 contains 119 pictures contributed as follows:—R. O. Milne, Esq., 14; Rev. W. Hancock, 13; F. Beasley, Esq., 9; T. R. Shervington, Esq., 8; E. Swinburne, Esq., 8; W. S. Hobson, Esq., 7; Rev. H. Palmer, 5; A. Watkins, Esq., 5; Capt. J. B. C. Fox, 4; W. Vanner, Esq., 4; Major Chadwick, 4; G. G. B. Creswell, Esq., 4; The Right Hon. the Lord de Ros, 3; R. Murray, Esq., 3; W. E. Gihh, Esq., 3; C. Stebbens, Esq., 2; J. H. Ritchie, Esq., 2; Major Herne, 2; W. Armstrong, Esq., 2; W. Muller, Esq., 2; Mrs. Deehle, 2; R. Leventhorpe, Esq., 2; R. O. Yearsley, Esq., 2; J. L. Ranking, Esq., 2; J. W. Richardson, Esq., 1; Mrs. Gulston, 1; J. W. Leigh, Esq., 1; P. B. Bury, Esq., 1; and F. Whitmore, Esq., 1.

Class 3 contains 95 pictures contributed as follows:—Rev. W. Hancock, 14; C. Stephens, Esq., 12; J. L. Ranking, Esq., 7; Rev. H. Palmer, 6; W. Muller, Esq., 6; Major Chadwick, 6; W. Armstrong, Esq., 5; Mrs. Deehle, 5; R. O. Milne, Esq., 4; P. B. Bury, Esq., 4; F. Beasley, Esq., 3; Mrs. Gulston, 3; W. Vanner, Esq., 3; A. Watkins, Esq., 3; The Marchioness of Anglesey, 2; Major Herne, 2; F. Whitmore, Esq., 2; The Right Hon. the Lord de Ros, 1; W. S. Hobson, Esq., 1; P. Gunyon, Esq., 1; Miss Cox, 1; R. Leventhorpe, Esq., 1; E. Swinburne, Esq., 1; J. W. Young, Esq., 1, and G. G. B. Creswell, Esq., 1.

The remainder of the pictures are comprised in Classes 4, 5, and 6.

Mr. GLAISHER remarked that it was most gratifying to find

the pictures for this year were not only much more numerous, but also far superior in quality to those of the past year.

Thus class 1 for last year contained 73 pictures, whilst class 1 for this year contains 111 pictures; class 2 for last year contained 94 pictures, and class 2 for this year contains 119 pictures.

The following prizes were then awarded: To R. O. Milne, Esq., for pictures 141 and 109, first prize, a large silver goblet; W. S. Hobson, Esq., for pictures 174, 175, and 180, second prize, a silver goblet; J. W. Leigh, Esq., for picture 37, an oil painting in gilt frame; R. Murray, Esq., for pictures 131 and 140, a silver goblet; F. Beasley, Esq., for pictures 302 and 303, a graphoscope; T. Brownrigg, Esq., for pictures 42 and 46, a graphoscope; J. W. Richardson, Esq., for picture 5, an oil painting in gilt frame; G. G. B. Creswell, Esq., for picture 6, an oil painting in gilt frame; R. O. Milne, Esq., for pictures 110 and 112, a graphoscope; E. Swinburne, Esq., for pictures 15 and 20, an oil painting in gilt frame; R. Leventhorpe, Esq., for pictures 8 and 9, an oil painting in gilt frame; the Marchioness of Anglesey, for picture 21, an album elegantly bound in morocco; T. R. Shervington, Esq., for pictures 26 and 27, an album elegantly bound in morocco; the Rev. W. Hancock, for picture 23, an album elegantly bound in morocco.

Certificates of honourable mention were awarded to Captain J. B. C. Fox, W. Muller, Esq., A. Watkins, Esq., W. Armstrong, Esq., and Major Chadwick.

ARTHUR J. MELHUISE, Hon. Sec.

MANCHESTER PHOTOGRAPHIC SOCIETY.

It was arranged that Saturday last, the 5th instant, should inaugurate the first out-door meeting of this Society (this season) in conjunction with the members of the Liverpool Amateur Photographic Association, at Miller's Dale, Derbyshire.

It was noticeable that none of those gentlemen (save the Secretary) who had the making of all arrangements as to time and place of meeting were present, but several others assembled, who, together with a few friends, mustered in all a party of fifteen.

Arriving at Marple, the station at which the Liverpool friends were to join company, great surprise was felt not to find any of them there; but on reaching Miller's Dale Station, the trail of two gentlemen from Liverpool was struck by accident, and they expressed agreeable surprise upon seeing the Manchester friends, believing the trip had been adjourned or abandoned. They explained that on the announcement of the meeting by the Secretary, they decided to be present; but a few days ago were informed that the meeting, as arranged, would not take place, and were told that no Manchester gentlemen were going; their presence there and then was attributable to an independent line of action with a view to spend the latter of the week in Derbyshire. They expressed much chagrin at having been misinformed, as many members of the Society had quite decided to attend, and would have been glad of the opportunity of an interchange of ideas and the pleasurable company of their Manchester friends. There could be no doubt their informant gathered his intelligence from somebody who had disseminated the rumour without authority, and so misled the members.

Despite every vexatious incident in connection with such a misunderstanding, the day was on the whole auspicious. Starting fairly, with the exception of a little wind, it proved a splendid photographic day.

Consequent upon the late heavy downfalls the roads were a little damp. But this and many dispiriting thoughts soon gave place to many agreeable incidents found in each other's company. After Miller's Dale had left its picturesque impressions upon upwards of twenty gelatine and other plates, the party had recourse to cheese plates and sandwiches. Soon afterwards a few more Manchester friends arrived (having come by a later train), when all set out to walk through Chee Dale, passing *en route* Chee-Tor and by Ashwood Dale to Buxton; and notwithstanding the Derbyshire miles were thought to be very much longer than Lancashire ones, the walk was spirit-stirring and enjoyable, being interspersed with incidents very pleasant and amusing in many ways. Having reached the Shakespear Hotel, speedy preparations were set on foot for a good substantial tea, all feeling in trim to do ample justice to excellent viands, and rising from the convivial board positively amazed at the wonders they had done under the invigorating air of those Derbyshire hills and dales.

Cameras of sizes varying from three inches square to 12 by 10,

and from one to 33 pounds in weight, were in the field; and plates of five different descriptions, fifty-seven of which were exposed, in addition to several excellent hand-sketches by one of the gentlemen present. This was brought to a close this field-day, and a red-letter day in the memory of those who had the enjoyment of each other's agreeable company, and who separated with the wish that it might be succeeded by many friendly and photographic gatherings.

Talk in the Studio.

THE MIRAGE.—The *Family Herald*, alluding to the Tenby mirage photograph, the particulars of which have appeared in our columns, says:—"It is an undoubted scientific fact, that, where there happens, from any meteorological cause, to be a stratum of atmosphere of considerably higher power than that immediately below it, the upper stratum acts as a kind of mirror, and may reflect objects at a very considerable distance. The most extraordinary instance of this phenomenon is the well-known case of Captain Scoresby, who, whilst engaged in the whale fishery, observed the distinct effigy of his father's ship suspended in the air, and thus ascertained the fact, of which he had been previously unaware, that his father was in the same quarter of the globe as himself. The vessel turned out to have been thirty miles distant when its refracted image was seen. In the hot countries of the South and East the mirage is frequently seen, and in the Straits of Messina it has acquired the name of the 'Fata Morgana,' from the ancient superstition of its fairy origin."

GELATINE has a peculiar action on gum; if gum be added to gelatine, and the mixture sensitized with ammoniacal potassium bichromate, the behaviour of the latter substance is very little altered by the addition of the former. Its solubility in hot water is somewhat increased, and to obtain the same degree of insolubility for the image as with pure gelatine the exposure must be longer. But if the mixture be acidulated with acetic acid, the film after exposure and desiccation is less soluble than one consisting of chromated gelatine only with acetic acid. Gum therefore renders an acid solution of gelatine less soluble, and the reason for this is believed to be that gluten and arabic acid form a compound solid only with difficulty. Barax thickens a gelatine solution, and the alkaline reaction of the same substance tends to render the chromated gelatine more insoluble. Calcium nitrate gives to gum an enormous power of adhesiveness.

PHOTOGRAPHIC RIFLE.—M. Marey having expressed a wish for the invention of the photographic rifle which could take instantaneous views of birds in their flight, Captain Eugene Vassel proposes a small dark rifle chamber of 35 millimetres (2.7 in.) interior diameter, surmounted by a proper level and sight. By means of Muybridge's, Janssen's, or other contrivances for taking instantaneous pictures, he thinks that small views might be easily taken which could be subsequently enlarged. He also proposes a photographic revolver for taking a series of successive attitudes at a single operation.—*La Nature*.

To Correspondents.

P.—We have no personal knowledge whatever of the project you mention, and hence have no means of knowing anything of its trustworthiness, either for investment or other business relations.

G. R. E.—The mottled effect of the piece of exposed paper you send is due to the use of a weak silver solution. Possibly the stock of solution was strong enough, but the appearance of the paper suggests that you have poured out a small quantity into a shallow dish, and sensitized several sheets of paper without replenishing; hence the solution has become weak by the abstraction of silver. It is desirable, after exposing several sheets, even on a large quantity of solution, to agitate the solution a little, otherwise the upper stratum of solution becomes weaker than that underneath, by abstraction of silver by the paper. It is wise to have the solution about an inch deep in the dish, at least.

OPERATOR.—Many operators undertake to retouch, but in large establishments it is generally considered an artist's duty. (2). Lead pencil is now in very general use for retouching, and gives generally the most delicate results.

R. M. L.—India-rubber is not a trustworthy mounting material. In the course of time it loses its adhesive property, and becomes a dirty looking resinous powder covering the back of the print, which leaves its mount. We should not use it even for placing prints in a scrap-book. A mounting material made by dissolving gelatine in spirit answers best for that purpose. The gelatine is first soaked in cold water, and then drained. It is then melted in a jacketed pan by the aid of heat, and methylated spirit is stirred slowly into it, a little at a time. We cannot tell you the precise proportions. It becomes fluid enough to use when very slightly warmed, and answers very well for the purpose.

F. W.—The original sizes of photographs were doubtless fixed to meet some mechanical convenience, possibly the covering powers of some existing lenses. At any rate, they were arbitrary. There is no good reason for adhering to them where they can be varied with advantage. Very often the proportions and composition of a landscape can be greatly improved by cutting a portion of the regulation size away, and in such case we should decidedly recommend it to be done.

X. Y. Z.—You have undoubtedly no right to exhibit publicly a portrait of one of your sitters against his expressed wish, and as a matter of business prudence it is very unwise to do so. Of course, when you have produced a choice picture, there is a temptation to show your best work; but you had better sacrifice your wish in this matter than quarrel with a customer on such a point in which you would be wrong.

W. M.—The iodides and bromides should be dissolved in alcohol before adding to the collodion. They will not readily dissolve in the collodion itself. Sometimes it is necessary to grind them in a Wedgwood ware mortar with alcohol to get them into solution. The potassium salts are not readily soluble. Cadmium salts are most convenient in this respect.

L. G. KLEFFEL.—So far as we remember, Dr. Moitessier's process was first communicated in brief to the French Photographic Society. It was subsequently published in detail in a pamphlet on micro-photographic, issued in Paris. Whether the pamphlet is now procurable or not, we cannot say. In our tenth volume (1866), on page 316, is a full notice of the matter. We will hand your new address to our publisher.

H. WALTER.—If you have a method of transferring the image to wood for engraving, better than using an image in fatty ink, we shall have pleasure in publishing it; or if you wish to sell the instructions, your announcement should appear in our advertising pages.

W. M. L.—We have no personal knowledge, not having made trial. As a rule, apparatus of all work has a tendency to do all the work promised, indifferently.

J. F. FULLER.—Many thanks. We have seen the instrument, and shall have something to say in our next.

J. FRANCIS.—We called at Red Lion Square, and saw your invention, and shall notice it shortly.

PYRO.—Your failure may arise from various causes, but from a description only we cannot form any precise opinion. It is possible that the silver solution may have got out of order. It is possible that you under-expose; it is possible that some actinic light finds admission into the dark room.

J. O. S.—It is evident that your bath has got out of order, but how we cannot tell you, as we, of course, have not had it under supervision. If the case were ours, we should simply make a new one at once, and, at leisure, convert the old one into silver. 2. The altered working of your toning bath suggests some impurities in the chemicals, in which case try fresh samples, or another formula for a change. But remember, slow toning is generally better than quick toning.

R. SYMONS.—You cannot get any copyright sanction for America, as no International copyright law exists between that country and Great Britain. The Fine Art Copyright Act only protects you in the United Kingdom, and beyond you have no protection.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

SUCCESSFUL PHOTOGRAPHERS IN ART AND IN BUSINESS.

WE take the first opportunity of commenting upon Mr. J. S. Tulley's letter in these columns a fortnight since, because it raises several points of interest which many would be glad to see discussed in wider terms. Whether our readers agree or not with Mr. Tulley's remarks, there cannot be a doubt about the frankness with which he writes; and although on reflection, possibly, he might have modified some of the views expressed, it is well at times that we should have a strongly pronounced opinion, even if it does not entirely coincide with our own. Mr. Tulley cannot be accused of beating about the bush; he has made up his mind about a subject, and has the courage to put forward his views without reference to the opinion of any one else. The points Mr. Tulley raises are well worth the notice of Photographic Societies, and if his letter has the effect of calling attention to some weak points in their mode of conducting business, the writer will probably be more than satisfied. We do not agree with what Mr. Tulley has written for the most part, nor do we think that Mr. Tulley ever expected that we should. That sound improvements and new processes of value can be brought forward at every meeting Mr. Tulley knows to be impossible, as much as we do; but he is ready to admit that "now and then something good is given by some persevering amateur who has both time and money at command." Not only this, but we should remember that, at any rate so far as the Parent Society is concerned, the greater portion of members are amateurs, or gentlemen, at least, who do not profit in a pecuniary sense from their photographic work. Professional photographers form but a small proportion of the members of the Photographic Society, while if it were only the exhibitions alone that this Society fosters, the benefits conferred would be great. But Mr. Tulley admits this, for after his sweeping condemnations, he says: "One Society, the parent one, is quite sufficient." In 1877, one of the most successful Exhibitions held in Pall Mall, the number of visitors who actually paid for admission amounted to 4,500, while some other 2,500 were admitted as members and friends. Thus we have an outside public of between four and five thousand persons made acquainted with the progress of photography—a point of importance that Mr. Tulley himself would doubtless be the first to admit. But, says Mr. Tulley, "no man of any particular standing ever come to the Society and say what they find out, by which they make their pictures and their fortunes by business." Mr. Tulley, in a word, wishes that any of his professional brethren—who, after all, make up but a small section of the members—that have been fortunate in business shall come to the Society and say how money is to be made. We remember a similar plaint made ten or a dozen years ago. We were dining at the Solar Club, and the conversation turned upon making money by photography. Our neighbour, like Mr. Tulley, wished some of the more successful members would enlighten their brethren on the subject of making money by photography, for he very much doubted if there was anyone at that time of speaking who had made ten thousand pounds in his studio. This conversation we repeated a day or two afterwards to a mutual friend, who told us that he could have put his finger upon one of the company, certainly, who had made that amount, and the person in question was no other than our friend at dinner. Now, shall we turn round and put our finger on Mr. Tulley? We rather suspect he has been a successful man of business, and could give useful hints on the subject of money-making. The only question is, whether, after all, we are not confounding two matters: good photography and good business qualities. The best photographer, if he is not

something of a man of business, will never make money; but it is with photography, and photography alone, that photographic societies have to do. We do not think there are two opinions as to the most artistic photographer in this country of recent years. The late Mr. O. G. Rejlander stood so pre-eminent in the photographic world, that his position has never been disputed. But he lived and died a poor man. We remember a quaint little speech he made on the subject of getting money. He advised his hearers to take up the glazed carte, or cabinet, after it had been elaborately retouched, to mount it on a cream-coloured card with a red border, and finish it as you see those elegant beauties upon a French plum-box. That is the way to make money; "but," said he, "it is not art." We do not tell our readers to follow Mr. Rejlander's advice; some of us are not artists enough to become his disciples in art-matters; some prefer to make money, and do so. The public in general will be found to care more for "plum-box" portraits than for any other, and it would be foolish, indeed, were photographers not to supply people with what they desire. But this did not concern Mr. Rejlander. He would have been glad enough, doubtless, could he have made money, but he lived very contentedly, nevertheless. Many will remember his picture of "Homeless," a boy asleep in rags and tatters on a door step, a picture which has been pirated by a dozen illustrated journals. Rejlander probably did not make forty shillings out of his work; but it is, nevertheless, one of the most successful photographs on record. His attention was called to the "sitter" by a policeman who was endeavouring to make the boy move on. "I said, here, bobby, put this namesake of yours into your pocket, and I'll see after the boy," was Rejlander's quaint account of the affair, and before he woke the boy, he had sketched the pose on a brown paper parcel he was carrying. But Rejlander, as we have said, would have been the last person to instruct one in business matters connected with photography. He accomplished very beautiful work, but was ignorant to the last degree in securing a sale for it. He had no idea of the value of time from a business point of view. He was mounting a print one day, awkwardly enough, no doubt, and required a pair of scissors to trim the photograph. He sent a little girl for the scissors, and idled away the time as he best could. But the messenger never came back. He waited and waited, until at last he grew impatient, and went out of doors to discover the cause of delay. It was a narrow court in Wolverhampton, black and grimy, and shut in on all side by sooty chimney pots. But a sun-beam had somehow lost its way, and got into the court, and when he looked out, there was his little fair-haired messenger standing on tip-toe, scissors in hand, and attempting to cut this sunbeam with her scissors, while she shaded the rosy light from her eyes with the other tiny hand. Rejlander spent much time in attempting to realize the picture afterwards by photography, but he frankly avowed to a painter subsequently that this was impossible, and that only upon canvas could the scene be reproduced. So that he lost his labour and his time in this case in fruitless exertions—another instance of unbusinesslike proceeding. But we doubt whether the experiences of successful men of business, if they would give them, would be so interesting, or even instructive, as those which the late Mr. Rejlander was wont to impart, while they would, as we said before, scarcely come within the scope of photographic societies.

ART IN PHOTOGRAPHY.

BY PAUL BROWN.*

IN response to a suggestion made by some of my photographic friends, I have prepared a paper on a subject which has been of vital importance to the artist. Beginning with his

* Communicated to the Chicago Photographic Association.

earliest attempts, the necessity of a proper support to his crude figures early presented itself, whether it be the undefined mistiness of an atmosphere, or a well-defined landscape, or the interior of a palace, a wood, or a hut. He early learned that the masses of light and shade must be so arranged as to properly support, and thereby enhance, the value of the subject. My earliest recollections of art are intimately associated with the wonderful process of portraying nature by means of the sun-picture, and I well remember the many ingenious devices resorted to, to produce the desired aerial background effect. Among the most remarkable, I mention one composed of a series of gauze screens set a few inches apart. This, however, did not produce a perfect atmosphere. The screens were next suspended and made to oscillate in alternate directions with each other. If my memory serves me, this nearly produced the desired effect, but was attended with disastrous consequences, inasmuch as the novelty frequently attracted the attention of the sitters, thereby spoiling the picture, which in the old Daguerreotype times was no trifling matter, as some of you, I doubt not, well remember. It was soon found that certain coloured coarse fabrics would produce the much-desired soft and delicate shade for the support of the figure, and at first were draped, but soon the flat surface took its place, hence the "plain ground," which soon became the accepted and only ground in general use for a number of years, the tint or particular shade of the ground always being in accord with the taste or peculiar idea of the artist which set it up. Scenic backgrounds began early in the history of photo-portraiture to attract the attention of the leading photographers in the East. As early as 1856, or about that time, an illustrated edition of Shakespeare was published in New York, embellished with the portraits, in character costumes, of the then living celebrities of the dramatic profession. About that time there arrived in New York, from Germany, a Mr. Henry Ulke, an artist who had made the improvement of the photo-portrait by means of retouching with india-ink his special study. This made him eminently the proper person to prepare those photographs for the engraver, and having been employed for that reason and purpose, not only refined the figure, but surrounded it with appropriate scenery, thereby making it doubly attractive. This suggested to the leading photographers a new industry, and one that must be employed and inseparably attached to the new art. Accordingly Mr. Fredericks, one of the foremost of the profession, secured the services of Mr. Ulke, at a salary of \$3,000 per annum, an amount which, at that time, and for that purpose, was of such magnitude as to call not only the attention of the fraternity to his establishment, but of the entire country who had interested themselves in the new art. Then Mr. Sarony, at that time a young man, and an accomplished lithographic draughtsman, turned his attention to this new department in art; with what success you all know. He is not only eminent as an artist, but has been awarded with a fair share of this world's goods. The embellishment of his photo-portraits are, in my estimation, amongst the very best ever produced. By this time, what was first looked upon as a novelty, had now become a necessity, so much so, that no first-class establishment could well hold its place without the assistance of a cultivated hand to soften, with ink, the harsh and angular lines of the photograph, and embellish the background with an appropriate design. Thus, by this new art, a fascinating and lucrative employment had been created, which for twenty years has been enjoyed by thousands of our art-inspired young men and women, and, for aught we can foresee, will continue for years beyond our wisdom to limit. In an interview with Mr. David Strong, a popular scenic artist of thirty years' experience, I learn that soon after Mr. Ulke's engagement with Mr. Fredericks he began to be called upon to paint scenic backgrounds by the photographers through the various towns of New England, where his engagements called him. But, as it was not a legitimate business with him, Mr. Strong waives all claim to being first in introducing the scenic background as now used, but gene-

rously awards to Mr. Ashe and his associates the honour of first making scenic backgrounds a special business, and largely introducing them to the fraternity as an acceptable accessory, through his agents, the Messrs. Anthony, of New York. Thus far, with all his success, Mr. Ashe has only for a more enterprising honour to sow and reap. To L. W. Seavey undoubtedly belongs the honour of successfully introducing and making the scenic background an indispensable accompaniment to any well-equipped gallery. His grounds combine the colour and touch that make them prominently without a rival. To him also belongs the honour of making it possible to introduce into the photograph accessories of every description necessary to complete a composition of almost any character, by actually manufacturing the reality of a light and durable material, which admits of easy and safe transportation and long use without injury. His is familiar to all; his reputation is not alone national, but world-wide. When the new and wonderful discovery was first proclaimed that a perfect picture could be produced by the action of sunlight on certain chemicals, it was predicted that the occupation of the miniature and portrait artist was gone. Time has not verified the prediction; on the contrary, it has been to them of the greatest assistance. It has made it possible for thousands to engage in and pursue the art of portraiture who, without its aid, would not have tried the venture. The fact soon developed itself that none but men of æsthetic tastes could successfully manipulate this new art. What has, or may be said to the contrary, it has been and is one of the greatest educators of the age we live in, and is nobly fulfilling its mission. In conclusion, allow me to add, this beautiful and scientific art has attained giant proportions. Among its votaries are numbered many of the ablest men of the world. To the amateur it is the most fascinating of the arts. Governments have captured it to mark the detailed progress in their internal improvements. It has become an indispensable ally of the astronomer and scientist. Its scope and use are too great to mention in a short paper like this. From its necessities have sprung a vast number of individual industries, and, with few exceptions, entirely unknown before its advent. If we are to judge its future by the past, we may safely say it is yet in its infancy. None are wise enough to determine the limit. These facts alone should be sufficient to inspire each of us to continue the reach for the highest possible excellence."

GERMAN CORRESPONDENCE.

BY DR. VOGEL.*

HARTMANN'S LECTURE 'ON ANATOMY FOR PHOTOGRAPHERS—DRY PLATES FOR DIAPPOSITIVES AND ENLARGEMENTS—GELATINE-EMULSION PLATES AND AMATEUR PHOTOGRAPHY—HOLTERMANN'S MAMMOTH NEGATIVE—PAPER NEGATIVES—FLUORIC ACID FOR CLEANING PLATES—SENSITIVENESS OF FLUORIDE OF SILVER—REPRODUCTION OF OIL PAINTINGS.

IN one of the last meetings of the *Verein zur Foerderung der Photographie*, Mr. Hartmann offered some interesting remarks upon anatomy. "Anatomy!" you will no doubt ask; "what has anatomy to do with out art?" It almost appears as if too much is expected now-a-days of the photographer—chemistry, optics, picturesque arrangement, posing, lighting; he is supposed to have a knowledge of painting, and now he is wanted to study anatomy. No doubt, many an over-burdened photographer, who sighed in this strain before hearing Mr. Hartmann's comments upon anatomy, changed his tune afterwards, for he learned that the construction of the human head cannot be understood without anatomical knowledge, and that only by acquiring some knowledge of anatomy he is enabled to avoid the many unpardonable and ridiculous mistakes which are now made in retouching. Mr. Hart-

* *The Philadelphia Photographer.*

mann gave the following amusing illustration of his remarks:—

“Some time ago, in conversation, a sculptor mentioned to me that he had been engaged to make the bust of a deceased person, of whom several good photographs were placed in his hands, to guide him in his work—a task which any first-class sculptor can well accomplish. There was one drawback, however, for the predicate ‘good’ could not stand in an artistic point of view, but was only accorded by the modern judgment of the public. The photographs in question were clean, sharp, glossy, and duly retouched, had been worked in the cameo-press—in one word, were excellent pictures, in the opinion of the public; in any case, they were idealized and flattered. The task of making a bust after them was, apparently, a thankless one. The sculptor, however, had some dim recollections left from his anatomical studies, which pointed strongly to the assumption that the human head contained some bones. But, according to the picture, the head of the deceased person had none at all. The forehead looked like a smooth billiard-ball, round, without any disturbing details, no prominent parts, plain surfaces, &c., and it was impossible to determine whether it represented a ‘short head,’ an angular forehead, one with concave or convex eyebrows. Was the forehead furrowed with strong or weak muscles, and were they bedded in fat, or were they lean? No answer to be got from the photograph! Were there any wrinkles on the base of the nose? Were the wrinkles of the apparently old head horizontal? Did they follow the form of the muscles and their movements, or did they cross them? No answer! Everything smooth, very clean, very prettily retouched and hot-pressed—the modern photography has surpassed itself; bones, muscle, and skin had disappeared, and only a beautiful, clean, and smooth tone had remained, from which the sculptor could make twenty-five foreheads, if needs be, with the slight exception only of the old, real, individual, and characteristic one.

“The nose, also, was spoiled through injudicious illumination. The eyes, which in reality had, perhaps, through age, become somewhat soft and diffused, appeared on the picture with sharply defined pupils, and, too, more boldly than happily-placed high-lights. The deep-set eyes, which probably could not have shown any high-light, appeared, therefore, bloated and swelled out like those of a lobster. The wrinkles near the mouth, the barrenness of the chin, even the characteristic expression around the corners of the mouth, had disappeared to the last trace.

“In spite of these deficiencies, there existed a certain resemblance to the original, as, of course, the contours of the head, and the settled relations of the whole, could not be retouched away, although the smooth, youthful skin on a relatively old head looked queer enough.

“Now, had the retoucher of that picture had even some slight inkling only of the construction of the human head, he would not have fallen into the grave error of making certain parts of the head disappear which are indispensably necessary to a man of life and blood. Or is it pardonable to round by retouching a forehead which is bulky and square? and are traits of the features which have been formed by the life-long influence of the character, and the sublying muscles, to be thoughtlessly retouched away, in order to make the picture appear smooth and clear? The picture can be cleaned in spite of these necessary little details, which impart life to a head, and all that is necessary in this respect is not to destroy the anatomically-correct aspect of the head.”

The carbon printing process, the general introduction of which seemed to be pretty well assured two years ago, is now, after having been tested by almost every practical photographer of note, very seldom used except for the production of larger pictures, especially for those of life-size, for which latter purpose it is extensively employed. Many photographers print from their negatives

transparent diapositives in carbon, from which they obtain in the camera an enlarged collodion negative, and from which, again, they print in the usual manner mostly in silver, and only seldom in carbon. The employment of the carbon process is therefore narrowed down very much, and it seems that recently another rival of it has come into the field.

The advantages of the carbon process for the production of the diapositives lie mainly in the wonderful rendition of the half-tones, which were never obtained with such an excellent success with the customary collodion process, or with the chloride of silver collodion. Recently, however, Mr. Wilde, a well-known dry-plate man, placed some dry plates in the market, which in the printing-frame lighted under the negative, produced directly, without developing, the picture far surpassing in brilliancy the most beautiful carbon transparent positives.

The carbon prints show, not unfrequently, some grain, while the new plates never show the slightest trace of that defect. They are so soft and beautiful that a picture enlarged from them cannot be distinguished at all from one taken direct from the subject. It is to be regretted that Mr. Wilde has not yet published the receipt for the production of his plates. He asserts that he uses collodion and gelatine emulsion, mixed together, which declaration sounds somewhat mystic. More about this in my next letter.

The science of optics makes, no doubt, fair progress, but it will hardly make such colossal strides in rapidity as the gelatine emulsion plates made lately. Of late the feverish excitement in regard to those plates has quieted down somewhat, as with the warmer season some difficulties arose, which have to be overcome yet, and I do not doubt that this can be done, as Colonel Dawson, in India, produced in 90° F., with success, gelatine plates, according to the report of the PHOTOGRAPHIC NEWS; and I do not see why this could not be done also here and in America. The gelatine plates in the market have given a new impetus to amateur photographing, and oftener than heretofore amateurs are met now at desirable points of view.

A very clever amateur here, Mr. Wight, explained to me the other day that he manages to get along in his travels without a dark-room, by simply using a clothes-closet, as it is found in every room of the hotels in Europe; but whether the landlords liked this novel use of the closets he did not state, and I doubt if they were ever pleased with it. In Switzerland, at one time, landlords only reluctantly took photographers into their hotels, because, they asserted, the chemical preparations were very injurious to the room and furniture.

You will remember the colossal panorama of Linden, taken by Mr. Holtermann, and which was on exhibition in Philadelphia. The same, thirty-two feet long, is now in Berlin, and has caused a great sensation here. Of equal interest is the enormous negative plate (probably the largest negative in the world), which was taken by Mr. Holtermann. It is 5 by 3 feet, and a copy of it was also in Philadelphia. I saw the original negative at Mr. Holtermann's place myself, when I had the pleasure to meet the gentleman at San Francisco. He brought it over with him to Hamburg, where he was born, and later on to Berlin, when he placed it, to my great pleasure, at my disposal, as he did not want to take it back with him to Australia. It represents part of the city of Sidney; and in regard to clearness and purity, the plate is very fair and satisfactory, which is the more remarkable, as Mr. Holtermann is also only an amateur; and hardly any other amateur will dare trying his skill on such an enormous plate.

As you well know, Mr. Warnerke, in England, has tried to supplant glass as a sub-layer for dry plates, with paper, and similar experiments have been made by a Mr. Sandner, of Teschen, who uses paper instead of glass in the wet process. The samples of his process which I had the

chance to examine answer every requirement, and are of special interest to Lichtdruckers, who want to copy the negative on both sides. The process has been patented, and will shortly be published in the record of patents.

The same Mr. Sandtner lately recommended a substance for use in the photographic laboratory which, till now, has been almost a stranger in it, namely, fluoric acid. He says that old and oft-used plates, which it was heretofore impossible to get clean again by any means, are cleaned so thoroughly by a treatment with diluted fluoric acid as to produce excellent negatives. The plates which have been used several times are first placed in strong potash lye, left there twelve hours, then washed well, and rinsed. Then they are put in diluted hydrofluoric acid (30 to 40 grammes liquid acid to 1 litre of water), which quantity suffices for more than one hundred plates. The hydrofluoric acid is furnished by the trade in bottles of caoutchouc, and, when cautiously handled, it is not so dangerous as generally assumed; and Mr. Sandtner states that he has often employed it in etching on glass, without meeting with the slightest accident. Before handling the bottle it is well to put on a pair of old gloves which have been soaked well in wax or turpentine. By bending the edges of a plate of lead a cup is made for the acid, in which the glass plates are placed, and rocked to and fro a couple of times. In a quarter of an hour the glass plates are taken out again, rinsed in pure water some time, dried in rags in the customary manner, and the plates are ready for use. Some brands of glass become somewhat dull by being cleaned with hydrofluoric acid, but this does not injure the transparency of the glass in any way whatever.

Speaking of fluoric acid, I will not omit to mention that Dr. Wolfram, in Dresden, lately made some very interesting experiments on fluoride of silver. This fluoride is, unlike chloride, bromide, and iodide of silver, easily dissolved in water. In regard to its sensitiveness to light the opinions differ very much. In Monckhoven's *Compendium of Photography* it is stated that fluor-silver shows a stronger sensitiveness to yellow rays than the above-mentioned silver salts.

Evrard asserts that fluor-silver sensitizes the iodine-silver plates to such an extent that instantaneous pictures can be obtained with them, and he adds that fluor-silver is sixty times more sensitive than iodine-silver. These statements must be erroneous, according to the researches of Dr. Wolfram. Fluor-silver superadded to iodine-silver produced neither shortening of exposure nor wrought any other advantage, and Dr. Wolfram even denies that in mixing nitrate of silver and fluoride of sodium, fluoride of silver is formed, stating that both substances remain unchanged side by side in the solution. Mr. Wolfram also did not perceive an increased sensitiveness to yellow rays in the fluoride of silver.

PHOTOGRAPHY AS APPLIED TO THE REPRODUCTION OF PLANS AND DRAWINGS.

BY DAVID TOWNSEND, B.S.*

THE various means by which drawings may be copied without the aid of a camera will, I think, be of interest to all, but more especially to draughtsmen and engineers, whose time is valuable, and whose dislike to making intricate tracings, proverbial. The different processes, which I will describe in detail, were all practised in my laboratory with a view to the adoption of the best by the works with which I am connected. I write, therefore, to benefit those who may be already on the road, or who wish to follow after. But, before passing to details, it would be well to consider the substances used as sensitizers, or picture producers, and the effect which light has upon them. This will enable us to better understand the chemistry of the processes, and perhaps point the way to new fields and improvements. The compounds most used to make a sensitive paper are chloride of silver, the persalts of iron and ura-

nium, and bichromate of potassium. These will be considered, with regard to the changes produced on them by light, in the order named.

Chloride of Silver.—Chloride of silver was the first substance noticed that changed by exposure to light. Its properties were known to the alchemists of the sixteenth century, who called it "lua cornua," but it was first brought to notice by the researches of Scheele in 1778. This celebrated chemist observed that whenever chloride of silver was exposed to light, chlorine was liberated, producing a blackening, and that on treating this black residue with ammonia, metallic silver was left behind. The present theory is that the chloride is reduced to the state of subchloride by the action of light, and free chlorine is liberated. It was also observed that when silver chloride was exposed in the presence of nitrate of silver the blackening was much more rapid, owing to the fact that the free chlorine liberated united with silver nitrate to produce fresh silver chloride. Thus we conclude that the sensitiveness is increased in proportion as there is a chlorine absorbent present. If, then, we sensitize a piece of paper, that has previously been salted, with nitrate of silver in solution, the sodium chloride will precipitate some of the silver as chloride, while the excess will still remain as nitrate, thus making a highly sensitive surface, and fulfilling all that is required for printing pictures.

Iron and Uranium.—The next salts we shall consider, in regard to their behaviour when exposed to light, are those of iron and uranium. Their reactions are similar, and we are indebted to Sir John Herschel and Niepce de St. Victor for the discovery of their peculiar properties. If we take two pieces of paper and brush them with a solution of ferric chloride, then expose one to the light and retain the other, finally flow ferricyanide of potassium over both, we will find that the one that was exposed will turn blue, while the other will remain unaltered. Now, as ferricyanide of potassium precipitates iron only in the ferrous state, we conclude that the action of light has been to reduce the ferric chloride (FeCl_3) to ferrous chloride (FeCl_2). By similar experiments we may say that the action of light on all ferric salts, under certain conditions, is to reduce them to the ferrous state. The conditions to which I refer are the presence of some organic matter, such as the paper, glazing, &c., because otherwise the reduction is exceedingly slow. This property of reduction by light possessed by all persalts of iron should be especially remembered, as it forms the basis of a number of processes whose details will be given hereafter. The action of light on the per-salts of uranium, especially the nitrate, is exactly similar to its action on iron—it reduces all uranic to uranous compounds.

Chromium.—The remaining metallic compounds which are of value as sensitizing agents are those of chromium combined with the alkalies. The alkaline bichromates, and especially of potassium, are, under certain conditions, far more sensitive to the action of light than either nitrate or chloride of silver. Potassium bi-chromate ($\text{K}_2\text{Cr}_2\text{O}_7$) by itself is a permanent salt, but when in contact with organic substances it quickly decomposes in the light. This property and its extreme sensitiveness render it invaluable to photography, in which it forms the basis for numerous processes, such as the carbon, Woodbury, photolithographic, &c. It is also the principal ingredient in the aniline process, at present much used in Europe for the reproduction of drawings.

Having thus seen the action which light produces on the different substances, we will now consider how we can best use their peculiar properties for producing photographic pictures. It would be well to mention here that in all cases, whatever the process, the operations of producing a picture are substantially the same. First, there must be a suitable support or ground on which the picture is to be produced, such as paper; second, the ground must be coated with substances, called sensitizers, which shall be sensitively affected by the light; third, chemical reagents must be

* *Journal of the Franklin Institute.*

used which will combine with and develop the image produced upon the sensitive paper; and, fourth, fixing agents, or chemical solvents, must be used that will dissolve all unaltered sensitizing agents, and make the picture permanent. Let us now consider the different processes.

Silver Process.—As was stated before, Scheele was the first to point out the effect which light had on chloride of silver; but Sir Humphry Davy, in 1802, was the first to produce a picture by the silver process; since that time it has made rapid strides toward perfection, and it is to-day the only printing process that has taken firm hold on practice. Of all the processes which I shall give, it is the most reliable, the easiest to govern, and yields the best results. The manipulations required are more numerous than difficult, and, after a little practice, become as easy as simpler methods. The operations, taken in their order, are as follows:—(1) Preparing the paper, or salting; (2) Sensitizing; (3) Exposing; (4) Washing; (5) Toning; (6) Washing; (7) Fixing; (8) Final washing.

1. *Salting the Paper.*—As the plain salted paper, which is invariably used for this process, is easily obtainable in the markets in sheets of any size, it is not necessary that time should be consumed in its preparation; but for those who are not convenient to any depot, or who wish to prepare it for themselves, the following directions will be of value. The papers most preferred are the Rive and Steinbach, but other brands of English and American manufacture will answer just as well for this purpose. If the paper be of the finest quality imported, the salting solution is composed of—

Ammonium chloride	1 part
Pure water	46 parts

but if it be the ordinary market article, or has not sufficient sizing, the solution should contain—

Sodium chloride	4 parts
Ammonium chloride	6 "
Sodic citrate	10 "
Gelatine	1 part
Pure water	460 parts

Sufficient of the solution must be made to cover the bottom of a pan to the depth of half an inch. The pan should be two inches larger each way than the sheet to be salted, and may be made of wood or tin, properly protected. It would be well to state here that all the pans, with the exception of the silver bath, can be made of tin thickly coated on both sides with asphalt, which renders them impervious to acids and alkalis. These pans be should made of a size to suit the largest drawing to be copied, and each operation should have a pan especially for that purpose. The salting bath is now poured into a pan, and all bubbles removed from the surface with a piece of paper; the paper to be salted is then taken between the thumb and first finger of each hand, at opposite corners, and curved so that on letting it down until in contact with the liquid, the centre line will touch first. The right hand is lowered carefully, and then the left, until the paper floats evenly upon the surface of the solution. If any air-bubbles are observed under the sheet, one corner is lifted and the bubbles touched with a glass rod. This is very important, otherwise the air, acting as a cushion, prevents the salting solution from touching the paper, and leaves a spot which will not become sensitive in the next operation. After allowing to float three or four minutes, the paper is raised by lifting two corners on the short side and drawing it evenly from the bath, after which it is suspended from a line by compression pins and allowed to dry. The process of swimming the paper, as described above, is also applied when sensitizing, and should be practised until perfection is attained. Care must be exercised in both operations not to allow the solution to flow on the back of the paper, as a black spot will be the result when it is exposed to the light. When the paper is dry, it is taken from the line, stamped or marked on the back, and laid away flat, to be

used as needed. A description of the preparation of albumen paper is not necessary, as it is seldom used for reproductions, and can be bought much cheaper than one could make it. For copying very fine engravings or architectural designs, it is sometimes desirable because of the brilliant finish and the pleasant color when toned.

(To be continued.)

SPIRIT PHOTOGRAPHS IN COURT.

THE Rochester Union says:—

"A singular suit at law has just been commenced in Dansville, R. L. Dorr having begun proceedings against W. J. Lee, a photographer of that place. It appears that Dorr came to Rochester a short time ago, and, hearing that the so-called spirit photographs were being taken at a certain place, went to try his success in securing upon the same negative with his own the faces of deceased acquaintances. He succeeded to his own satisfaction, which we will presume was the more easily obtained because of the fact that he was before a firm believer in Spiritualism. On returning to Dansville he became involved in a controversy with Lee regarding the matter, and the latter volunteered the opinion that the whole business was a humbug, and that he could demonstrate his position to the other's satisfaction. It is stated that Lee made a trial, and afterwards abandoned further attempts. Dorr sues for this breach of contract, but claims that he does not care so much for the value of the picture as he does to establish the fact that photographs of spirits are actually being taken. The trial will take place on the 22nd inst., and it is expected that a large number of witnesses from the photographers, the clergy, and the medical profession will be called. The Dansville Express, in commenting upon the alleged phenomenon, says: 'To produce upon the same negative plate, at the same time, a setting of familiar faces other than the sitter, involves a mystery not yet solved by the knowing ones, and we are waiting expectantly to know what manifestations are to come next.' It remains to be seen what the legal trial referred to will develop, but it is to be hoped that it will be sufficiently thorough and exhaustive to set many minds at rest on this question."

THE MANUFACTURE OF PHOSPHORESCENT SUBSTANCES.

A CORRESPONDENT of the *Scientific American* writes concerning the phosphorescent powders found on luminous clock dials. Having ascertained by analysis that this phosphorescent matter is nothing but sulphide of calcium, you say there must be something or other in the mode of manufacture of this substance to give it such a brilliancy as has never been obtained before.

Being in situation to know much about this subject, I think it will be agreeable to you if I give you some details on this question.

The phosphorescent matter of the luminous dials is prepared in Paris; the maker is M. André, 39, Rue Laëpède. Twenty years ago, being famulus in Mr. E. Becquerel's laboratory, he was taught by him how to prepare phosphorescent sulphides, and then began to make them for the chief instrument makers in Paris.

The first products obtained had but little intensity; but gradually M. André became more and more skillful in his work, and three years ago he was able to produce the substance you have seen on the dials. Such a wonderful result was obtained only by carefully studying the mode of manufacture, and depending only on a few tricks of hand. This I can affirm, but I cannot give you the details of the manipulation, which are kept secret.

M. André does not make only the blue violet powder used for dials; this colour has been chosen for that because it keeps luminous a longer time. But the results are almost as good with yellow, yellow-green, green, and orange powders.

SOME NOVELTIES.

INVITED recently to pay a visit to Messrs. Marion's establishment in Soho Square, we there saw some novelties a brief mention of which will interest our readers. Our duties, whilst usually separate from the commerce of photography, can never be antagonistic, and are often closely associated with commercial aspects, where the interests of photographers are concerned. Hence we always feel a deep interest in every novelty which may give a stimulus to photographic trade prosperity.

Cadett's pneumatic shutter is now familiar to almost every professional photographer in the world, and has been very largely adopted in all kinds of studios. Introduced but a comparatively short time ago in this country, it was rapidly adopted by English portraitists, and has since been as cordially adopted in France, and other parts of continental Europe, and also in America. The one drawback which was occasionally urged against its absolute perfectness was the fact that the shutter was outside the lens, and its movement might at times distract attention. From the first it was pointed out that it might easily be adapted for inside use, but some mechanical difficulties made this not quite convenient. It has now been made, as Messrs. Marion showed us, expressly for inside use, all difficulties being eliminated, and the action perfect. The movement of the shutter, which is now placed immediately at the back of the lens, is very rapid, yet so gentle that there is no risk of disturbing dust, even in a very dusty camera, a thing which should not ever be found in any studio. The most restless child, or the most nervous sitter, may now be exposed without seeing a movement to distract or disturb the attention; in fact, the exposure may proceed without the sitter's knowledge or consciousness. The additional convenience secured does not add to the cost of the instrument. The arrangement is so simple that, with the instructions supplied, every photographer may easily fix the shutter for himself.

The next novelty brought under our attention consisted in some charming specimens as illustrations of a new size and style in portraiture, entitled the promenade portrait. We speak of the size as new, inasmuch as it is so to English photographers, although, if our memory serve us aright, the size and name were introduced some little time ago in America, and mentioned in our pages. The mounting and *entourage*, which are decidedly new, are very charming and effective. The size of the unmounted print is $7\frac{1}{2}$ inches by $3\frac{3}{4}$ inches. The dimensions of the mount are $8\frac{1}{4}$ inches by 4 inches. The print is mounted like a card within one-eighth of an inch of the edge at the top and sides, leaving a five-

eighths margin at the bottom. The black mounting card is a stout one, the edges being bevilled and gilt. The size especially fitted for standing figures, either male or female, and is especially effective for the very long flowing draperies of the present mode in ladies' dress. The size of plate for negatives is for single plates, eight inches by four and a-half, and for a double negative eight inches and a-half square. A size handy in every photographic establishment, the ten by eight, might be made to answer well for the double plate. Mounts, albums, and a very charming series of frames for the new size, are all provided, and we venture to predict for it a fair share of public favour. Probably at no former period did professional portraiture more require a stimulus to induce new life and activity, and any taking novelty calculated to aid in effecting this ought to receive a glad welcome.

Another aid to effective portraiture consists in some very admirable accessories in *papier mache*. These are of high class and excellent design. Too many of the accessories of this kind which have been employed in photography have been trumpery and inartistic in design, and without any harmony in their combination, classic and gothic, ancient and modern designs being mingled without the slightest trace of knowledge of the incongruity. Most of these under notice are modelled from well-known originals of high repute. Here is a series from Haddon Hall, balustrades, steps, &c. A piece modelled from a grand old tree is also very fine. A column presenting the fluting of the classic column on one side, and the clustered columnation of the gothic at the other side. The texture, colour, and general effect of these are excellent.

The "Soho collodion" is another novelty, with much excellent promise, which can only be verified by testing, and upon which we can, therefore, say nothing at present. A preparation for securing a retouching surface locally without treating the entire surface of the negative seems a useful idea. Of its efficiency we cannot speak. Of the very extensive stock of admirable photographic appliances we need not make any detailed notice here.

Another novelty is to be found at Mr. Solomon's warehouse in Red Lion Square, where we saw it at the request of Mr. Francis, of Rochford. It is entitled the photo-chromosome. It is an instrument for viewing lantern or stereo transparencies, and glorifying them by the addition of glowing colours. They are placed in a hollow cylinder, an enlarging lens in front, and beyond the slide is placed a glass cylinder coloured in sections with various tints. The light passing through this coloured cylinder reaches the transparency, and as the coloured cylinder is revolved, fresh tints illuminate the picture, giving varieties of sunshine and shade, dawn, sunrise, sunset, night, and moonlight. The effect is exceedingly pleasing, and the means very simple. Mr. Francis has protected his invention by patent.

FRENCH CORRESPONDENCE.

SOME REMARKS ON THE EMPLOYMENT OF THE ELECTRIC LIGHT FOR PHOTOGRAPHIC PURPOSES—ABILITY TO DISPLACE THE ACTINISM OF DIFFERENTLY COLOURED RAYS—A NEW IMPROVEMENT BY MONCKHOVEN IN THE GELATINO-BROMIDE PROCESS.

Some Remarks on the Employment of the Electric Light for Photographic Purposes.—My honourable colleague, who alternately with me contributes the French Correspondence to the PHOTOGRAPHIC NEWS, in his letter published in your issue of the 27th of June, takes up the subject of photography by the electric light, and mentions the dispute which has arisen as to the rights of M. Vander Weyde to the sole possession in France of the system which he has patented; he also states that it is M. Liebert who has purchased the French patent of the employment of the double reflection of the electric light, and that no other

person but he is entitled to the legal right of using this system. M. Versnaeyen also alludes to an article which I wrote for the *Moniteur de la Photographie* on the subject of the photographic *seance* by the electric light which was arranged by M. Pierre Petit at the Opera House on the occasion of the charitable fête in behalf of the sufferers by the Szegedin inundations. The author of the above-mentioned letter seems to think that I have not exhibited an impartial spirit in discussing this question, but that I have ranged myself on the side of M. Pierre Petit in the dispute, and in opposition to M. Liebert. He further accuses me of not having published the protest which was addressed by M. Liebert to the Editor of the *Moniteur de la Photographie*. Fortunately, I am in a position to give a complete answer to these assertions. First, then, the photographic feat which was accomplished at the opera fête seemed to possess so great an interest for those engaged in the profession, that I hastened to obtain as perfect an account of it as possible, in order to describe the process in the columns of the journal of which I am the Editor. Secondly, I gave the information just as I received it, with the exception of some condensation: the actual words used were: "Our fittings originate entirely with ourselves, nothing belonging to them is patented or patentable, and our professional brethren are quite at liberty to obtain for themselves commercially the same instruments as we have ready for use." Thirdly, no letter of protest was received by me before the 1st of July, the day on which the *Moniteur de la Photographie* appears, though, as I have since learned, M. Liebert addressed one to me on the 19th of June. Fourthly, the number of the PHOTOGRAPHIC NEWS containing M. Versnaeyen's letter was only received by me eight days after the date of publication, and, after reading it, I at once wrote to M. Liebert, and explained to him that I had no motive for taking a side in a dispute which could have nothing but a commercial character; that, in fact, I had been no more than a channel for the communication of intelligence which had been furnished to me. Lastly, in answer to my letter, M. Liebert forwarded to me a copy of the protest, which had been lost in the post, and this will be published in the next number of the *Moniteur de la Photographie* on the 15th inst. If my honourable colleague, before writing his letter for the PHOTOGRAPHIC NEWS, had only sent me a single line asking for information, he would not have laid himself open to the imputation of bringing a charge which—though no doubt made in all sincerity, and due in a great measure to a couple of mistakes of the post—the foregoing explanations have shown to be unfounded. I take this opportunity of declaring that I never mix myself up with quarrels resting on purely trade questions; their proper jurisdiction is a legal tribunal, and they in no way concern me. My part is to treat a disputed point on entirely technical grounds, whether of art or of science, and as I have quite enough to do in that direction, I have no inclination to touch upon interests of another kind, which cannot be dismissed without raising personal questions. It is the business of M. Pierre Petit to come to terms with M. Liebert, as there is already a lawsuit between them; it is for me, acting on that line of impartiality which has been and is my habitual and regular rule of conduct, to keep myself quite outside the dispute—after giving publicity to M. Liebert's protest, for that is nothing but justice.

Power of Displacing the Actinism of Various Coloured Rays.
—Some time ago, in connexion with a paper read before the Photographic Society of France by M. Cros, I took up for a while the subject of the possibility of producing plates which should render correctly the real value of the radiations from a luminous body, and I then believed, and stated my belief, that the question of obtaining the relative values in negatives was one of the most important in the whole region of photographic science. More mature reflection, however, has convinced me that there are many

cases where this effect, so ardently wished for, would lead to nothing but deplorable results. Let us suppose that it is wished to reproduce with the same actinic value a picture in which certain colours of equal force as regards tone, but presenting to the eye well-marked differences—as, for instance, blue, yellow, and red—from three adjoining surfaces. In consequence of the equality of the actinism of these three colours, different as they may be in appearance, the photographic result will be a surface of equal value taking in the whole of the three surfaces of different colours. Modelling which is effected in this way in an oil picture would be converted in the reproduction by photography into a flat surface; the same thing, indeed, often happens with ordinary collodion when one chances to have a subject modelled in colours of equal actinic value—such as carmine, light blue, and light grey. With these three colours a subject can be very clearly modelled, but the negative taken from it will not present the same shades of difference as this modelling. In the reproduction also of subjects from nature, there will be prominences and depressions causing more or less intense shadows, an effect produced by the colour of the objects; but in this case the appearance of a reproduction executed in a medium which equalizes the actinic values would be that of a plaster statue. As all the colours act equally, there would be nothing left but the action, more or less intense, of the luminous rays after reflexion. In the case of a painting a similar treatment would not be available, since we have here a plane surface completely modelled, so that every gradation would disappear, and there would remain nothing but a kind of grey image without effect of any sort—without those pleasing contrasts which make the beauty of the photographic reproductions of paintings, in spite even of the falseness of some of the tints, which often substitute sombre tones for the luminous ones of the original. The ideal that we must place before us is to produce the effect of a chalk drawing, similar to an artist's copy in crayon of a picture. But how is this effect to be obtained? How shall we succeed in producing clear modelling when we have in front of the objective a subject whose half tones are formed by an aggregate of colours all producing the same effect on the sensitive film? Will it not, on the contrary, be necessary in such a case to find some means of re-rendering the actinic values unequal—to force, in fact, the blue and the rose, which have the same actinic value, but which produce so very different an effect on the eye, to reproduce themselves photographically, with a difference of action equivalent to their difference in appearance? If any one will take the trouble to think this over, he will soon see that the problem is much more difficult of solution than at first sight he would have any idea of. From considerations such as these, then, we are led to conclude absolutely that a process which would enable us to reproduce the solar spectrum in the form of a perfectly white band without the demarcations that characterize the red, the yellow, the green, &c., would be the worst process that could be conceived for the reproduction both of pictures and of natural objects; but that does not mean that there is no improvement to be effected in this direction, nor that all should be left as it is now because nothing better can be done. There is more especially to be sought for a means of bringing out the details in the shadows as in the most luminous parts: in the reds as much as in the blues, &c. And here at once we can lay our hands on an important auxiliary in the shape of sensitive films of great rapidity, like those of gelatino-bromide, with the further condition that the plate may be submitted to the action of light until the exposure has become sufficient to obtain the effect of even the most refractory colours. By developing we shall obtain a negative well defined in every part, but grey and transparent; in this state it would give indifferent positives; but by reinforcing with some gradually-acting medium, we can intensify to any

required degree without danger of smudging. And now I shall probably be asked, Will the green come out to the same extent as blue? Fortunately I am able to reply, No! If the green develops in an equal degree with the blue, and the yellow with the red, we should have an image of a whitish appearance representing rather a plaster cast of the natural object, than the object itself, with all its infinite variety of tone and colour. For my own works in photochromie, a result of the kind indicated would be highly desirable; but outside of this special application I do not think that it will be necessary to seek for a means of equalising the actinic values of the different colours. And when we have artificially produced a negative with the relative values which photochromic impressions require, we shall, by taking prints from it in monochrome, produce nothing but pictures of the most miserable and unpleasant appearance. We should perhaps, therefore, rather seek for a solution in the contrary direction—that is to say, in the dissimilarity of the actinic effects produced by the colouring of exactly the same actinic value. The circumstance above mentioned, that a more complete result may be obtained by over-exposure, will be found to be corroborated in a recent work of my excellent friend Dr. Monckhoven, and also by the observations of Captain Abney, Dr. Eder, and others. It is due to the fact that a longer exposure of sensitive films of gelatino-bromide does not, as is the case with wet collodion, expend its force in producing solarisation of that part of the spectrum which lies between the blue and the violet; on the contrary, its action is extended in the direction of the less refrangible rays beyond the sodium lines—that is to say, beyond the yellow, and even so far as the orange. The red is the most refractory, but we can even produce an impression of that part of the spectrum by prolonging sufficiently the time of exposure. Impressing our minds with these considerations, which I have endeavoured to render as clear as possible, we arrive at the conclusion that, though the displacement at will of the actinic action is a subject well worthy of investigation and experiment, it must not be sought for in the direction indicated above—that is, in the equality of the effects produced by the differently coloured radiations—but rather on the contrary road, or in the inequality of those effects.

Improvement in the Gelatino-Bromide Process.—As I have just spoken of my friend Monckhoven, I may perhaps be excused for committing an indiscretion in alluding to a new discovery of his before he himself has made it public; the result of his remarkable experiments on the preparation of gelatino-bromide is, that he makes his emulsion at one operation without any final washing. I can scarcely say more at present, but the process itself will soon be divulged by the author, and it will then be seen that he has made a great step in advance towards the realisation of a practical result capable of being worked on a large scale.

LEON VIDAL.

ON SOME RED AND YELLOW PIGMENTS FOR COLOURING THE WINDOWS OF THE DEVELOPING ROOM.

BY DR. J. M. EDER AND CAPT. TOTHI.*

ABOUT two years ago we published our investigations of the property which *chrysoïdin* possesses of cutting off the chemically active rays, and we showed that leaves of gelatine stained with that substance do in effect cut off the actinic rays (the blue end of the spectrum), but not so completely as glass coloured red with cupric oxide. Our experiments at that time were made with silver bromide emulsion plates, which were developed by the alkaline method. Dr. Vogel performed the same experiment with iodo-bromide of silver plates, but found the action of *chrysoïdin* to be not so favourable, for it allows some of

the violet rays to pass, and wet plates are more sensitive to these than dry bromide films. Especially in the region of the spectrum near the lines H' and H" Dr. Vogel observed that light admitted through a *chrysoïdin* film produced a chemical action. More recently we have examined with the spectroscopic collodion and gelatine films which had been deeply stained with *chrysoïdin*, and found that they permitted the green-yellow, the yellow, and the red rays to pass, none of the blue or violet ones.

To prove the permanence of *chrysoïdin* to the light, we exposed for fourteen months a sheet of gelatine stained with that substance. At the end of that time the colour had nearly disappeared, or had been converted into a purplish tinge which admitted the blue and violet—that is, the chemically active rays—freely, while another sheet kept in the dark, but in contact with the air, had undergone no change. A piece of paper coloured with *chrysoïdin* faded completely in the light, and turned quite white. Beneath a combination of yellow and green glass, which admits the red, yellow, and green, but not the blue and violet rays, neither the stained gelatine nor the coloured paper lost its colour; only the blue and violet rays, which are those the most largely absorbed by *chrysoïdin*, destroy the colour, while the red and yellow produce no effect. The orange-coloured light which passes through *chrysoïdin* varnish or gelatine also produces no effect on *chrysoïdin* paper.

Notwithstanding that *chrysoïdin* admits a portion of the green, it is to be preferred to fuchsin or aniline red. A varnish or collodion stained with the last-named substance admits a large proportion of the violet rays, even when the film is deeply coloured.* Only very thick films, which in the case of varnish are difficult to obtain, keep out violet light. When fuchsin has faded by exposure to light (the fading is probably due to the blue rays), a still larger proportion of the violet and blue is admitted. No. 1 of the accompanying table of the absorption spectra shows

1. Anilin red. 2. Ordinary yellow corallin (aurin). 3. Red corallin (pœonin). 4. Dragon's blood, concentrated solution. 5. Anilin red and corallin. 6. Ruby glass coloured with copper. 7. Ruby glass coloured with gold. 8. Cobalt glass and ruby-copper glass.

the behaviour of aniline red in a ruby red film of collodion or varnish.

As regards *corallin*, we would, in the first place, point out that the yellow variety of that substance—called, also, aurin or rosolic acid—differs both chemically and spectroscopically from the red variety or pœonin. The former, which is the ordinary product of commerce, is soluble in alcohol and ether, but not in water; the latter dissolves in water as well. Yellow corallin, when sufficiently concentrated, absorbs the whole of the violet, the blue, and

* *Photographische Correspondenz.*

* As artificial lamp light contains but few violet rays, the experiment must be performed in sunlight.

the green-blue parts of the spectrum as completely as ehrysoidin, and can be used for the same purposes as the latter—for instance, for colouring the paper in which sensitive bromide emulsions are packed. It is cheaper and more readily procured than ehrysoidin, and less affected by damp; but, unfortunately, it also possesses the defect of fading gradually on exposure to light. On the other hand, the red corallin does not cut off the violet rays (see No. 2 and No. 3 of the accompanying table), and cannot be substituted for the yellow corallin when the object is to stop out all the actinic light.

Dragon's Blood, which is rather more permanent, and was formerly much used for the preparation of a yellow varnish for the developing room, will not, when sufficiently concentrated, admit any green-blue, blue, or violet light; but it allows more of green light to pass than corallin does, and when dilute it even admits some of the blue—a consideration which must not be neglected. Galatino-bromide emulsions are so sensitive to green light that the latter must be completely excluded from the developing room, and only the red and orange admitted, for even the yellow rays are injurious.

To secure immunity from the reducing action of light, it is best, as pointed out by Abney,* to employ a combination of two or more colouring materials, and his exhaustive treatment of the subject renders unnecessary a discussion of most of the pigments on our part. We desire, however, to recommend especially a combination of the very prevalent aniline red, which completely absorbs the blue-green, the yellow-green, and part of the yellow, but allows the violet to pass with dragon's blood, corallin, or ehrysoidin, which cuts off the blue and violet. The two pigments thus complement one another to a certain extent, as will be seen on reference to the table. A combination of aniline red with corallin (No. 5 in the table) absorbs all the rays except the red and orange, and approaches closely in non-actinic power to the ruby-copper glass (No. 6); the combination acts more completely than any single pigment alone. Paper stained with such a mixture is a good protection against actinic light, and is a perfect substitute for ehrysoidin. The colour must, however, be intense, or the absorption of light will not be complete.

But films of varnish, collodion, or gelatine stained with organic colouring materials can never thoroughly replace coloured glasses, for the latter are even in tone and permanent in colour—that is, will never fade. Let us first consider the glass flashed red with copper; this cuts off the violet, blue, green, and part of the yellow rays, provided it be too light in colour. For the window of the developing room, only the glass stained red with copper must be used, not that stained red with gold, for the latter allows part of the blue and green to pass. The difference between the two is shown in the absorption spectra Nos. 6 and 7 of our table. Finally, we would refer to the best combination of all—that of blue-cobalt glass and red-copper glass—which is fully described by Abney in the above quoted paper. The deep red rays of the spectrum only are admitted by this combination, as shown in No. 8. In every case before glass for the dark room is selected, it should be submitted to microscopic examination. Such an examination is easily effected, a piece of the glass of a few square centimetres in size being quite sufficient for the purpose.

A FEW HINTS USEFUL IN THE PRACTICE OF GELATINO-BROMIDE PLATES.

BY A. J. JARMAN.

IN drying the gelatino-bromide plates, as described last week, my experience has been that the best plates are obtained by allowing them to dry either spontaneously or with the cold draught through the drying-box, and that

plates prepared in this way are all the better for being kept for some time.

I will give an instance. Last April I prepared a batch of plates, all of which were packed away in the common wooden plate-boxes. About nine days since I hunted my dark room over for an extra two dozen quarter-plate box, and found one among a lot of paper clippings. Upon examination, I found two dozen excellent plates of the most rapid description. I immediately tried one, and, to my utter astonishment and joy, I found it worked all right without methylated spirit or anything else to prevent the frilling. This box of plates was reserved as a treasure for children's portraits. All have worked well—no frilling whatever. One was a mishap. Thirteen of them have realized me £4 3s., and five remain.

Several photographers have said to me, "But don't you find the use of methylated spirit expensive?" I replied, "You had better use half-a-pint of methylated spirit, and secure a good negative, than to lose half-a-guinea for a dozen cartes." Not one of these plates requires an exposure exceeding a second in decent light. I have found that plates prepared with emulsion that has been kept for a few days, and dissolved in hot water instead of lukewarm water, are sure to frill. If this should unavoidably occur, pack them away in a box, and forget them for a month or two; in that time you will find them all right, and fit for any work. To be sure of getting your plates always good, too much stress cannot be laid upon always melting your emulsion at the same temperature it was digested at.

The specimens enclosed will, I think, bear me out in all I have described of this most beautiful process.

PERSPECTIVE FOR PHOTOGRAPHIC STUDENTS.

BY J. MARTIN.

MY last paper concluded with some remarks upon vanishing lines. These vanishing lines regulate the height and breadth of every object in the picture, and also produce the effect of what is called foreshortening; and where they converge too rapidly they produce the distortions instanced by the hat in the sitter's hand before mentioned. I remember a ludicrous instance of this in a pictorial comic Christmas card. The centre of some musical whaits (all looking extremely uncomfortable in the midst of a snow storm) is playing upon a cornopian which is so directly foreshortened that the observer can see nothing of it but its mouth, seemingly surmounted by a rough fur cap; beneath are a pair of short bandy legs and abdomen seeming as if they belong to a frog. The inequalities of surface of the ground plan of a picture often causes ludicrous mistakes, such as a man firing at birds he cannot see, water flowing up hill, and various others. One of the most difficult things for a beginner to draw, giving each line as a problem in foreshortening, is an overturned sitting-room chair lying endways towards the observer. It being quite impossible to enter into such an abstruse science as perspective to any great depth under present circumstances, I should recommend the learner to obtain some familiar treatise upon the subject. With this view, I mention Hayter's Catechism, and Thenot's Perspective, of which I believe there is an English translation.

Either of these contains sufficient information for the use of a photographer; but there are others much more voluminous, treating perspective as a mathematical science. Although a picture may be drawn with truth in just proportion with talented design, and in true perspective, still the objects there represented will bear but a faint resemblance to nature, even with the addition of light and shadow; but add colour, and then we may believe we can smell the blushing rose and taste the luscious grape. Of simple colours—that is to say, as they are sold

* See PHOTOGRAPHIC NEWS for 28th March, 1879, page 146.

by colourmen—seldom or ever are any introduced into a picture; but the whole colouring of the scene is toned to represent the character of the occasion, and any colour introduced of a different tone will look disjointed, and be said to stain. The brighter in colour the greater in degree will this effect be produced. For good examples of tone, the landscape of Cuype and Claud Loraine may be particularly noticed. The tone of the picture must of course vary with the different peculiarities of the country to which the scene belongs, as well as the time of day, the time of year, &c. If the picture represents an interior, the tone that will pervade it must be in unison with that of the source of light which it receives; but a picture—for instance, a night scene—may be partially lighted by the moon, and partly by a fire.

Correspondence.

THE MIRAGE.

DEAR SIR,—As the above phenomenon is very seldom seen in this country, possibly a few lines may not be uninteresting. The case of Captain Scoresby, referred to in the PHOTOGRAPHIC NEWS last week, is not an isolated one.

Whilst engaged as photographer to the West Indian and Panama Telegraph Company's expedition in 1870-71, I had occasion to notice this phenomenon on several occasions—notably the following.

We had laid a cable from Santiago (or St. Jago), and part of our party had gone to Batabano, some miles from Havana, for the purpose of connecting the intermediate cable with the shore ends. With them (as convoy) went a Spanish gunboat (our convoy was H.M.S. *Vesta*). We were left at a place called Diego Perez—not a harbour, but a shallow place where we had buoyed the cable until our party should signal through the cable they had gone to connect that all was well. However, they did not succeed for some weeks, and we were getting short of fresh provisions, which the gunboat was to bring to us.

One afternoon, about four o'clock, we were astonished at seeing (of course, through the marine glass) what was the exact counterpart of the aforesaid gunboat, only reversed and high up in the sky, although the distance was computed at from twenty-five to thirty miles; still we could even make out her flag, which was a very large one. At that time nothing could be seen of the vessel herself; but the image gradually came down to the horizon; soon after her mast seemed to touch the water, and then the whole suddenly disappeared.

Shortly afterwards the vessel herself appeared, and in about two hours after we had a fresh meal on board.

If this is of any interest at all, I should add that I tried to take a negative of the image (as I had a permanent dark room on board); but at such a distance, and the ship rolling about so much, and the only lens possible to get even a microscopic picture, I was totally unable to obtain what would certainly have been a most interesting *souvenir* of my voyage in the West Indies.—I am, dear sir, yours truly,

ALBERT S. WITHERS.

3, Wyndham Street, Bryanston Square.

A WORD TO MY BROTHER OPERATORS.

SIR,—In last week's paper, "Mass," in a telling letter upon photography as a business, used a sentence that kindled an old fire in my breast. He speaks of employers who engage an operator and want him to do a little of everything, which literally means everything—general utility, in fact, and at starvation prices. He likewise adds that, unfortunately, the number of such employers is great.

My experience confirms that last assertion—their name

is legion! They are the fungus of the profession—they crop up like weeds—they swarm like a pestilence! Generally lacking education and devoid of natural talent, they eke out the position with the eye of the lynx and the craftiness of the fox. Having reared their glass-house and puffed its good qualities in the local papers, they next cast their eye upon the advertising columns of the photographic papers. It is a hundred to one if they answer an operator in want of a situation! Nay, they are more artful than that. Mark this, my brother operators! You will find the class I allude to advertise in all the grandeur of a Baker Street studio. The applicant must be thoroughly efficient, of gentlemanly appearance and manners, a first-class retoucher, and his character bear the strictest investigation. Of course, he has to send carte of self, and specimens.

From such an advertisement the best dis-engaged talent in the profession applies. Some one more unfortunate than his compeers is answered. Negotiations are entered into. If the applicant is married, so much the better for the shrewd employer. He next, perhaps, worms out of him that his means have sunk as low as his spirits, and consequently a bargain is struck that sinks the operator below the level of a labourer, both in his own estimation and in his pecuniary emoluments.

Do not blame the operator: his wife and children must have bread, and he jumps thankfully at the offer, laying the flattering unction to his heart that it is only for a time, and that something better will turn up for him by-and-bye. But, poor fellow, he does not see the day after day of down-right slavery; the nagging and worrying of discontented customers and the watchful eye of his master, who sucks his little arts and secrets from him—in short, who is learning of him, and who, when he thinks he has learned all, will turn him adrift in the same manner as he would brush the dust off his coat.

That is a fair sample of our bogus employers. The evil and harm they do to our class is incalculable. Four years ago I came from Northumberland to Exeter to fill an engagement as first-class operator and retoucher, at a salary of £1 15s. and five per cent. on all takings, to find that I had engaged to a man of the lowest order, whose principal takings were in shilling pictures. He misled me—purposely deceived me—wrote to me as if his place was first in the city. Bluntly I told him what I thought, and, of course, quarrelled, so that at the end of the first week—Heaven, save the mark!—he discharged me. I had his letters, for he did not engage me in a hurry, and I fancied that I had a hold upon him. Armed with them, I went to the magistrate, and explained my case, but only to find that nothing could be done. Certainly the magistrate expressed deep indignation at the manner I had been used; his words were very consolatory, but I had spent my last £4 to take my wife and child with me, and now I was left with one week's wages to find another situation.

It is a pity that truth is a libel, for I should so much like to publish that man's name, and warn you against falling into his hands; for I have it from reliable authority that I was not the first, nor have I been the last, that he has served in the same manner—aye, and worse!

One sure sign of this style of employer, and one well known, I have no doubt, to my fellow workmen is, that they never return specimens. It is hard to lose your best work, but, my friends, console yourselves with old Dogberry's philosophy, and give thanks that you have so easily got rid of a rogue.

Now, after mature thought, I have come to the conclusion that the only way of lessening their power, and curtailing their facilities of obtaining good men to cheat, is for the said good men to unite, and, after using that word, I have only to mention our poor, struggling Benevolent Society.

I have penned the above in the hope that it will awake some of you to a sense of your duties, as "Mass's" letter

did to me; for I must honestly confess that I am a fair sample of the old but expressive saying of, "When the devil was sick"—for when money was scarce, and work hard to find, I made vows innumerable that the first spare coin should make me a member; but, here I am, very well off, and my vows forgotten. I dare say it is the same with a number of my brother operators; but let them wake up, and say with me, that before another week goes round there will be a new member, and his name will be, yours truly,

GEORGE BARDFORDE.

47, Milson Street, Bath.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF IRELAND.

The first meeting of this Society was held at the Queen's Institute, Melesworth Street, Dublin, on Wednesday, the 9th instant, the President, Professor J. EMERSON REYNOLDS, M.D., in the chair.

The President, having congratulated the Society on the success which had attended its formation, expressed the pleasure it gave him to see such a large attendance of members present.

Mr. J. V. ROBINSON communicated to the Society his experiences of the gelatine bromide process, and showed the actual development of some gelatine plates of different descriptions.

At the close of his paper, many questions were put by the members anxious for further particulars on certain points, with a view of comparing the experiences relative to the manufacture of the emulsion, showing the warm interest which is taken just at present in all matters connected with this fascinating process.

A number of negatives and transparencies having been examined by the members, some surprise was manifested at the wonderful results obtainable by gelatine when photographing subjects totally outside the range of the wet collodion process.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

At a recent meeting, President NEWTON in the chair, the minutes of the last meeting were read by the Secretary and approved, subject to some corrections.

Mr. MASON said: I have here a plate of glass which is something of a curiosity. It was left in an alkaline solution inadvertently for some three or four months, and the effect of the strong alkali upon the surface of the glass is somewhat remarkable, giving by reflected light all the spectrum tints fully as brilliant as it is possible to produce them by any other means with which I am acquainted, while the surface is eroded, so as to render it worthless for photographic use. I also exhibit again the prints which were made by the Committee of the Section on May 19th, 1874, and in the toning of which Mr. Newton's method was used for eliminating the hyposulphite after fixing. It was suggested to me by Mr. Anthony that it might be as well to show them at this time. I have kept them put up in this condition between glass—but not sealed—for convenience in handling. They have been made now nearly five years, and were shown at one of our meetings two years ago. They have been exposed to light in due part of that time, the light shining on them when the sun was in the right direction. Mr. Anthony was on the committee, and he suggested the use of permanganate of potash in the same way or similar to Mr. Newton's way of using lead; and this print exhibited, a portrait of the sculptor Carl Müller, was fixed as suggested by Mr. Anthony, and indorsed on the back of the print, as some of the members of the committee may remember, if any are now present.* It seems to have kept pretty well.

Mr. NEWTON: The feature of difference between the mode in which the hyposulphite was eliminated from these and the ordinary one was that the hyposulphite was decomposed by the lead solution in a very few minutes—about five being all that is necessary to render the print entirely free from hyposulphite. Not a trace could be discovered by any test we could

* Mr. Mason has made a mistake in this. The method I suggested, and which was tried at the time, was the substitution of a salt of barium instead of the lead salt. The permanganate of potash was only used as a test for the presence of hypo. after the use of the lead salt.—H. T. ANTHONY.

apply; whereas prints from the same lot that were left in running water all night, by careful test showed hyposulphite in the morning. The fact that they do not fade in five years after exposure to light, but appear to be as perfect as when they were first finished, is a matter of some importance, as silver prints have the reputation of fading or not being permanent.

Mr. MASON: The whole method was published at the time, or soon after, in the photographic journals, so that any one interested can easily find the full report of the committee upon the method.

Mr. CHAPMAN: I have here some coloured glass which I have been testing the non-actinic power of in a general way. I have only three specimens. One is a ruby which Mr. Mason has alluded to at some of our previous meetings, which I have marked No. 3; another, which is an orange, marked No. 2; and some glass which has been coated with an aniline colour in a film of collodion, marked No. 1. In certain classes of work with the spectroscope, it is desirable to suppress certain parts of the solar spectrum which overlap other parts, and at the same time diminish the light of the parts required to work on as little as possible. For this work I had found the aniline-coated glass to be considerably the best. This No. 1, you will observe, obstructs much less light than the others; but on examination in the spectroscope I found that it cut off all the more refrangible part of the spectrum from about half way between E and b, at a wave length of about 47,900 per inch. This is in the green; there was no blue to be seen. By reference to this coloured diagram which I have here you will see where these lines are located in the spectrum. Through No. 2 I could see the F line in the blue green, which has a wave length of about 51,500 per inch; and through No. 3, the darkest ruby, I could see the blue distinctly, could see lines having a wave length of about 53,200 per inch. I was somewhat disappointed with this glass, as it let through more green and blue than I expected, and I also found it selective in its action. It cut out nearly all of the yellow between the orange and green, and let through the green quite strongly, and some of the blue. From these results I judged that the aniline-coloured film would be the best for the photographic dark room. I therefore gave Mr. Mason the three specimens to try. He first tried them on the ordinary sensitised albumen paper, when, to my surprise, the No. 1 printed through first. This induced me to go a little further with the experiments, and I had him try a negative with his ordinary collodion bath. We then found the No. 1 to be much the more non-actinic; No. 3 came next, and the orange the least of either. Then an emulsion was tried, with results similar to the last, but not quite as marked between the aniline (No. 1) and ruby (No. 3). It will be observed that No. 1 is much the lightest in colour. I find it takes fully three thicknesses to obstruct as much light visually as the ruby does, and at the same time one thickness is much less actinic with the iodide and bromide silver salts. From these few trials it appears that it was the yellow light which did the work on the chloride paper. I would also remark that the emulsion showed more exposure in twenty seconds than the bath plate did in one and a-half minutes.

Mr. NEWTON: At the last meeting I exhibited a lens with a drop in the tube for instantaneous work. I have a print made from a negative taken of a street view from the roof of my residence. The reason why I brought it mainly was from the fact that it was developed with the oxalate developer. In the minutes read of our last meeting, it was perhaps noticed that I said something about the oxalate developer, expressing an opinion—more my impression, perhaps, rather—that it was more active, more potent than the alkaline developer. The oxalate is an acid developer. I have not had an opportunity to carry my experiments as far as I would like to, but I am still of the same mind, or the impression has been strengthened in reference to the oxalate developer as a developer by which a picture can be developed with much less exposure than with the alkali. This print that I show you is from a negative made with a pair of Morrison's new stereoscopic view lenses, with the second opening, developed with the oxalate developer. You can see that the cars and people were on the move.

Mr. NEWTON introduced Mr. Fontaine to the meeting, who exhibited to the Section two lanterns, one for opaque pictures and one for transparencies, and explained their properties. After the exhibition the President said he would like to have an expression of opinion of the performance of these lanterns as compared with the one exhibited by Mr. Taylor at the last meeting. One of the reasons why I would like an expression

of the views of those present is this: something of this kind should be owned by the American Institute for this Section; and a lantern lit with an oil lamp, if properly constructed, will answer all the purposes for which we want a lantern. We do not want to give an exhibition to entertain or please an audience; what we want is to test the quality of positives or transparencies and other photographic work by various processes. Something of this kind will answer all the purposes for which we need such an instrument. I would like to have a committee appointed to attend to this, and find out the best lantern of this description, or something of the kind, and to make a report at our next meeting. The lantern which Mr. Taylor kindly exhibited at the last meeting was a foreign-made instrument; but he can inform us about the necessary process to obtain one, if the committee should decide that that was the best. I would like to have some one offer a resolution that a committee be appointed to take this matter into consideration, also the means to have one permanently belonging to us.

Mr. MASON suggested that, at the meeting in June, other lanterns might be exhibited, and the Section would then be better able to judge. He had seen a lantern which the parties exhibiting it to him claimed was superior to any other before the public. If it could be got for the next meeting, the Section could judge. He asked Mr. Taylor the cost of the lantern exhibited by him at the April meeting.

Mr. TAYLOR replied about three or four pounds English.

Mr. FONTAINE stated that his firm make three sizes: one that takes a half plate, price \$10; the second size exhibited sells for \$20.

Talk in the Studio.

PHOTOGRAPHIC SCENERY IN A MUSICAL ENTERTAINMENT.—Those of our readers who have the good fortune to know Mr. F. A. Bridge, the esteemed treasurer of the South London Society, know that the sister art of music shares with photography his energies and interest. In a new programme of the series of musical entertainments he has prepared to place at the disposal of literary and other institutes and societies, we find one entitled "Gems of English Scenery and Song," in which transparencies from photographs of English landscape scenery by Mr. William Brooks will be exhibited in the "tridiaphanout," or now triple oxyhydrogen lantern. The very high quality of Mr. Brooks's landscape work will doubtless aid in giving beauty and interest to Mr. Bridge's excellent musical entertainment.

PHOTOGRAPHIC SOCIETY OF IRELAND.—We are pleased to hear that this Society has been started under the most favourable auspices, and with a much larger number of members than was anticipated. A report of the first meeting will be found on another page.

A NOVEL WAY OF OBTAINING A PLEASANT EXPRESSION has lately been successfully tried by Mr. C. W. Davis, Athens, Ga. Mr. Davis has trained a canary to sing upon a given signal. When about to remove the cap from the instrument, he gives the signal to the bird, which at once bursts forth in a sweet song. The sitter forgets all about the head-rest, the trying light, the wearisomeness of keeping a fixed position, &c. (all of which complaints are familiar to the photographer's ear). A pleasant and unconscious expression on the face of the sitter is the result of the little bird's melody. The idea is a good one, and, we think, might be put in practice by others.

BLACK POLISH ON IRON AND STEEL.—To obtain that beautiful deep black polish on iron or steel which is so much sought after, it is required to boil one part of sulphur in ten parts of oil of turpentine, the product of which is a brown sulphuric oil of disagreeable smell. This should be put on the outside as slightly as possible, and heated over a spirit lamp till the required black polish is obtained.—*Scientific American.*

BEAUTIFUL BLACK COLOUR FOR BRONZE.—A strong concentrated thin solution of nitrate of silver is required for this purpose. It should be mixed with an equal solution of nitrate of copper, and well shaken together. The pieces which require colouring are dipped into this solution and left for a short time. When taken out, they should be equally heated till the required black colour makes its appearance.—*Ibid*

To Correspondents.

J. BAILEY.—Wash the prints before toning in salt and water. The simplest toning bath, of the kind you desire, is made as follows: take one grain of chloride of gold in solution, and make it into a creamy paste with precipitated chalk, then pour eight ounces of hot water on it, stirring well. When the solution is cold it is fit for use. We always keep chloride of gold in solution one grain to the drachm. When we open a 15-grain tube of chloride of gold we at once dissolve it in 15 drachms of alcohol. The precipitated chalk you will obtain of a chemist under the name of "prepared chalk."

G. YOUNG.—Undoubtedly. The Lambortype processes are patented, and the Autotype Company are the owners of the patent. The Company will doubtless give you information what their patents cover and protect.

H. TAUNT.—The markings in your negative are perplexing. We never met with any such; but we have frequently had examples sent to us with enquiries as to their cause. We believe them to be due to floating scum on the nitrate of silver solution.

TYRO (Brighton).—Your letter was unfortunately mislaid, or it would have been answered last week. We regret, however, that we cannot give any very precise answer. It is possible to commence a photographic business on such a variety of scales that it is impossible to estimate the cost of such a step. You might commence moderately with a capital of one hundred pounds, and you might, with advantage, spend a thousand. The prices of the best lenses you will best learn from catalogues. If you send to Mr. Morley, of Islington, a dealer in first-class second-hand apparatus, for a catalogue, you may form a good idea of the apparatus required, and of the cost at which you may obtain it second-hand.

H. J. DAVISON.—The proposal to paint the interior of the studio "orange pea-green" originated in America, and we published all the details given. We have no means of asking the author any questions on the subject, as his communication was made in an American journal, and an American agent for the paint was mentioned.

DABUCA.—It is quite certain that no one can attain a copyright in your photographs without an assignment from you of such copyright, nor can any one legally register and claim a right in them. Your agent in London, by getting the Act, and taking steps in accordance therewith, can doubtless secure you a remedy.

AMATEUR.—There is no treatise on enlarging cameras published. Many descriptions of individual enlarging cameras have been published in our pages, and may be found on searching through the volumes. If you have or can procure a set of our YEAR-BOOKS you will find much information on the subject scattered through their pages. Camera makers, to whom photographers look for the construction of such things, rarely publish treatises on the subjects.

CHAS. SNOW.—You will find full details of Mr. Bennett's developer and mode of using it on page 512 of our last volume, Oct 25th. 2. If you had described your mode of enamelling, we could probably have pointed out where the fault was. There are various methods of proceeding, and we don't know which you used. The irregular mottling and the tearing of the glaze are both due to imperfect contact between the print and the gelatine. Probably the prints were not properly wet when placed in contact with the coated glass plate, and not properly squeezed down.

A. J. JARMAN.—Thanks for the further very excellent examples of gelatine work. We shall be pleased to receive details of drying box, ruby lantern, and digesting kettle.

A. B.—The proportion of hyposulphite is not of vital importance; one ounce in six ounces of water will answer. You may add seven ounces to a quart of water.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AT LONDON-SUPER-MARE—THE PAGET COMPETITION.

Photography at London-super-Mare.—If London photographers have cause to complain just now of "depression of trade," the plaint can hardly be made by those in London-super-Mare. A visitor to Brighton just now cannot fail to be struck with the bright and prepossessing looking studios in the King's Road and elsewhere. We know, of course, that in this country it is not only in the capital that photographers of the first rank congregate, but that at the chief watering places they are unusually conspicuous. Mr. H. P. Robinson, of Tunbridge Wells; Netterville Briggs, of Leamington; Nesbitt, of Bournemouth; and Hughes, of Ryde, to mention a few good names at random, are examples, and in this respect, we believe, our country differs from France, Germany, and Continental nations generally. The Paris photographers, those of Berlin, and of Vienna, are unequalled by any of their brethren in the provinces; with us, on the contrary, in certain fashionable places of resort, photographic portraits are executed every bit as well as in the metropolis. Of course it is only photographers of *premier rang* in the provinces who thus compete with their brethren of Regent Street and Baker Street, but that first-class work is to be met with elsewhere than in London is a fact that needs not to be dwelt upon. The reason for this is not far to seek. When people are pleasuring they usually hold the purse-strings loose, and sitting for one's portrait, for some inscrutable reason, is counted among pleasures. So that Mr. Brown, of London, who holds half-a-sovereign to be sufficient payment for a few cartes of himself, has no objection to spend twice or three times the amount when Mrs. Brown and the Misses Brown are with him spending a few weeks out of town. Whether the family goes to Tunbridge Wells, or to Brighton, or across the water to Paris, they leave behind them that prejudice about the half-sovereign, and as they are willing to pay more, it naturally pays a first-class photographer to settle down in such places. We have mentioned Paris, because a large amount of work by Paris portraitists is done for the English, who, when they afterwards point to their French pictures as being double as good as those they had taken at home, omit to point out the fact that they cost double as much. At Brighton, as we have said, there are many fine studios. Mr. Mayall, who, our readers may remember, held the proud position of Mayor of Brighton last year, still enjoys the position of premier photographer in the queen of watering places. Mr. Mayall's studio is in the King's Road, and as he spares neither money nor energy to keep abreast of the times, it is no wonder that he is still a successful man. But he has to march quickly not to be left behind in the race, in which he has taken a part for a longer time than we care to remember. Mr. Mayall has happily got together a very fine series of celebrities, or rather of their portraits, for there are few of our great men and women who have not come under his notice and that of his camera. An especially fine portrait of Disraeli—or, rather, Earl Beaconsfield—another of William Black, the well-known novelist, and a third of the late Mr. Lewes, essayist and novelist, are among this gallery of notables. Messrs Henrah and Kent, and Messrs Lock and Whitfield, have also studios in the King's Road, where small delicate work, of the Williams and Mayland school, as it might well be designated, is executed with exquisite finish. These two firms, situated close together, appear to have made a bargain with one another as to the class of work they will execute, and neither strives to out-do the other with showy elaptrap performances. The finish and pose

of the pictures in both cases testify to the art and technics of photography having been perfected to a high degree. M. Lombardi has also a studio in Brighton; he aims more to secure brilliancy and vigour in his productions, as does also M. Boueher, whose portraits at the Pall Mall Exhibition two years ago will be remembered by our readers. Another studio, a few doors from the Old Steyne, deserves also to be mentioned, that of Mr. Donovan, who was, if we mistake not, but recently the manager of M. Boueher. Mr. Donovan appears to be particularly happy in his depiction of children; there is a charming roundness in the modelling of the little limbs, and none of his sitters have that weariness of expression which is very common to infantile portraiture. Mr. Donovan displays, too, a good deal of the artist in his Rembrandt vignettes, some of which he executes with rare taste. There are other studios in Brighton that could be mentioned, scarcely, if at all, inferior to those here set down, for, as before remarked, the number of good businesses in London-super-Mare betoken a very healthy sign of the prosperity of photographers here. Glass-rooms, as is the case of those of many other watering places, are to be found here on the ground floor, and there is not that disagreeable "getting upstairs" which is well-nigh inseparable to London studios. A two-fold reason may be found for this. In the first place, space being not so valuable out of London, room for a ground floor studio is more easy to obtain; while, again, a photographer at a spa or health resort calculates upon having a large proportion of invalids among his sitters. To ask a lady or gentleman who lives in apartments on a flat to save the trouble of ascending and descending, and who passes most of the day in a bath chair, to mount three or four flights of stairs, is out of the question, and photographers who desire the custom of such invalids must, of course, provide for their comfort. Mr. Robinson's fine suite of retiring and reception rooms and studio at Tunbridge Wells, and Mr. Hughes' Regina House at Ryde, are two model establishments in this respect.

The Paget Competition.—The Paget £50 prize seems to be giving the jurors some difficulty. It is now some months since the competing candidates sent in their various plates and processes, and we know that the referees have already done a good deal in the way of examining the proposals sent in. But it must be remembered that the task imposed upon the jurors is no easy one, and it is a question, obviously, requiring much time and patience to settle. We are unaware of the number of competitors or the extent of the investigations to which the award committee are committed; but seeing that the object Captain Paget desires to secure is a dry process that, while it is trustworthy, is simple and capable of being worked by an ordinary individual who has given some attention to photography, it is very evident that a searching investigation must be made. As to securing a very simple and reliable method, one that shall give no trouble and always yield good pictures, we can only say to photographers, that we wish they may get it. However, if there is such a thing knocking about in professional or amateur studios, we certainly think that the means taken by Captain Paget is likely to unearth it.

HOW TO USE EMULSIONS.

BY J. SALOMON.*

It would not be a kindness to the reader to occupy his time with a description of the innumerable methods by which collodion emulsion is prepared, because, on the one hand, its manufacture requires great experience and special preparations; while, on the other, it can be purchased ready prepared at a low price and of a degree of excellence

* *The Photographic Times.*

to which the tyro in chemistry could never hope to attain.

Plates ready sensitized by emulsion collodion are now extensively sold; indeed, it is scarcely saying too much to assert that all the sensitive dry plates that are sold are prepared by one or other of the emulsion processes.

Emulsion photography therefore naturally divides itself into two parts: the method of using such emulsion as can be purchased in preparing dry plates by its means, and the method of developing emulsion plates, no matter by what means prepared, or whether they have been made by the photographer, or purchased.

If the emulsion be what is termed "washed emulsion," it will have its organifier or preservative mixed up with it, and in using it, the mere act of pouring it upon a glass plate suffices to render such a plate ready for exposure, either immediately or after several months. If the emulsion contains an excess of soluble bromide, the plate coated with it will not be ready for exposure until it has been immersed in a vessel of water to wash it, and be subsequently treated with a preservative. As "washed" emulsions are now supplanting all other kinds, we shall begin by explaining in what way it is to be used.

The plate of glass having been cleaned, it is advisable, previous to coating them, to give to them either an entire substratum, to prevent the collodion film from leaving the glass during the subsequent operations, or to coat the margin of the plate in a similar manner. A useful solution for this purpose consists of four or five grains of india-rubber dissolved in an ounce of benzole. This, when poured upon a clean plate, leaves an exceedingly attenuated film of rubber upon the surface; but thin though it be, it insures the adhesion of the collodion film. If an edging only is to be applied, the india-rubber solution should be much thicker (say about the consistency of collodion), and it should be applied by means of a camel's-hair brush. Many do not coat their plates with a substratum applied either in whole or in part, but content themselves with sprinkling over the surface a little powdered French chalk which, when rubbed briskly over the plate, gives such a quality to it as to cause the collodion to adhere with all the required tenacity. The emulsion must be poured upon the plate slowly and with deliberation, and run from corner to corner, the superfluous emulsion being poured back into the bottle. To prevent it from drying in ridges, the emulsion must be drained off at one corner, and after having been kept in that position for such a time as to insure the collodion having dripped off, the plate must now be tilted so as to stand in a vertical position. This position must be maintained until the ridges first formed quite disappear, when the plate may be reared up to dry, after which it is ready for use, and may either be placed in the store-box or in the dark slides of the camera.

If an emulsion having an excess of soluble bromide be used, the plate, after having been coated, must be placed in a vessel of water to be washed, after which it is immersed in a ten-grain solution of tannin, and then dried. Instead of tannin, an infusion of coffee or tea may be employed with advantage. But this kind of emulsion is seldom now used.

To Develop an Emulsion Plate.—The plate is first attached to a pneumatic holder, and a little methylated spirits of wine poured over the surface so as to wet it all over. Allow this to act for about a minute, during which time you are mixing in a suitable cup the developing solution. This having been done, wash the face of the plate by means of a stream of water, until the greasy appearance caused by the spirit disappears. This treatment with spirit and water opens the pores of the collodion film, and enables it to be penetrated by the developer.

Each manufacturer of plates has his own way of conducting the development, but while there are apparent differences in the instructions sent out along with the

plates of each respective maker, the real difference is so very slight that any one developer will suit the plates of all makers.

The composition of every one of the alkaline developers is restricted to three classes of ingredients: pyrogallic acid, ammonia or other alkali, and bromide of potassium or other soluble bromide. The pyrogallic acid develops the image, the alkali gives it vigour and force, while the bromide checks the action and prevents fogging. With this general explanation we now enter into details.

One of the best methods of developing a negative, especially for beginners, is that in which he is enabled to feel his way at each stage, and adopt precautionary measures to obviate the effects of over- or under-exposure. Proceed thus:—

Pour over the surface of the plate (which is now wet) enough of a four-grain solution of pyrogallic acid to cover it. Then watch attentively the appearance of the image, which comes up very faintly. Should it not appear in the course of a minute, add to the pyro solution one drop of diluted ammonia, composed of one drachm of ammonia to twelve of water. This will cause the image to appear. Now observe the character of the picture. If it appear to be flat and over-exposed, check the action by adding to the developer one or more drops of a ten-grain solution of bromide of potassium. This checks the further developing, but permits the image already developed to acquire intensity. On the contrary, should the feeble image first brought out show indications of under-exposure, this must be remedied by prolonging the action of the pyro, and adding more ammonia solution, refraining from using more bromide than suffices to prevent the fogging of the shadows.

By following these hints a beautiful negative can always be obtained, even when the plate has been a little over or under-exposed.

It is convenient to keep a concentrated solution of pyrogallic acid in alcohol. Also, instead of liquor ammonia, carbonate of ammonia may be used. The following formula has been much employed, and gives good results. It is that of Colonel Wortley's.

A.—Pyrogallic acid	96 grains
Alcohol	1 ounce
B.—Carbonate of ammonia	64 grains
Water	1 ounce
C.—Bromide of potassium	16 grains
Water	1 ounce

These are kept in separate bottles, and, when used, are mixed in the following proportions:—

Water	1 ounce
A	30 drops
B	40 "
C	10 "

This is poured on the plate as the iron solution, and the picture flashes out at once.

Another good developer is composed by

Washing soda	1 ounce
Bromide of potassium	2 grains
Ammonia	2 drachms
Water	10 ounces

This is first applied to the plate, and is afterwards poured back into a measure, in which a quantity of pyrogallic acid, about the bulk of a pea, has been placed. When this is returned to the plate the image comes out very evenly.

It is generally not desirable to give the plate its full intensity by the alkaline developer, but to do so with acid pyro and silver. The proportions are:—

Pyrogallic acid	4 grains
Citric acid...	3 "
Water	2 ounces

After the image is developed and washed, a little of the

above is poured on, and then one or two drops of a twenty-grain solution of nitrate of silver is added. Take care not to make the image too dense, because, being of a non-actinic brown colour, a negative that appears thin often prints strongly.

Fix in a saturated solution of hyposulphate of soda.

To Develop Gelatine Plates.—This is done precisely the same as the collodion emulsion plates, omitting the first application of alcohol, using water only. Mr. Kennett's formula is as follows:—

N Mix in the following proportions—

- o. 1. To 4 grains of pyrogallic acid, 1 ounce of water.
- No. 2. To $\frac{1}{2}$ -ounce of the strongest liquor ammonia, 8 ounces of water.
- No. 3. To 3 drachms of bromide of potassium, 8 ounces of water.

Mix 2 and 3 together in one bottle; (they keep better in this state than separately), and proceed as follows:—

Pour over sufficient of No. 1, to which has been added one drachm of the mixture Nos. 2 and 3 to each ounce of No. 1. The image will now in a short time appear, and gain in strength; at this stage of the development any amount of density may be obtained by adding one or two drops of plain ammonia and water, of same strength as No. 2. When of sufficient density, wash well, and fix in hyposulphate of soda, strength four ounces to a pint of water.

SENSITIZING TISSUE FROM THE BACK.

BY H. J. BURTON.*

SENSITIZING tissue from the back has so many advantages, that I think a few words pointing them out may be acceptable to carbon workers. I will first of all remark that to produce the finest work in carbon requires the same amount of care and cleanliness as for the production of spotless negatives.

When the tissue is received from the makers, it should be cut up into sheets of convenient size, and stored between boards; in that condition it will be found much more easily manipulated subsequently. What size to cut it will depend upon the requirements of the purchaser—30 in. by 18 in. would be a very good size to handle, cutting strips across the hand 18 in. wide. In handling tissue, a pair of knitted white cotton gloves should be worn. Having the tissue in flat sheets, we will now sensitize it, with the following solutions:—

Water	20 ounces
Liquor ammonia	1 ounce
Bichromate potash	4 ounces.

Mix the ammonia with the water, then grind up the bichromate and dissolve in it.

Have a flat board, larger than the sheet of tissue to be sensitized, and cover it with blotting-paper, and on that lay the tissue face downwards, first dusting it and the blotting-paper with a flat camel's hair brush. Now pour out a small quantity of the sensitizing solution into a saucer, and, with a sponge of good size, wet the back of the tissue evenly with the solution for (say) three minutes, and hang up to dry in a room where there is a fire, but taking care to let the back of the tissue be presented to the fire, and at a distance of about six feet from it. There will be little chance of its running, except the weather happens to be exceedingly hot.

The advantages claimed for this method of sensitizing are:—The tissue may be used much sooner after sensitizing, on account of the small amount of liquid absorbed, as by applying the sensitizing solution at the back a much stronger solution may be used without any fear of its crystallizing upon the surface of the tissue. No fear of running in hot weather.

* Autotype Notes.

The face of the tissue (which in every case must form part of the picture) is kept perfectly clean, as no particles in the bichromate solution can settle upon it, and the fact of no free bichromate being upon the surface of the tissue would have a tendency to give it better keeping qualities. Large sheets can be sensitized, and no large dish or large quantity of solution required.

A solution of bichromate of potash undergoes no change; but if once used for sensitizing tissue a slow decomposition commences, which in time forms an incrustation upon the inside of the bottle in which it is kept; no doubt caused by the solution dissolving some of the constituents of the tissue when immersed in it, and, if used frequently, is a certain cause of insoluble tissue.

CAUSES OF FOGGING.

BY O. W. OSBORN.*

MUCH has been said and written by those well posted in photography, relative to the importance of keeping everything neat and clean in the studio, and especially in the dark-room; yet a glance at some of the dark-closets in the smaller galleries would suggest that such instructions and teachings by the older heads in photography had been calculated to serve the purpose of pleasant Sunday reading, by perusing which the photographer might wile away a few leisure hours, instead of heacon-lights placed upon the shores of the vast sea of photographic perplexities to guide the weary artist into the distant haven of photographic intelligence.

The dark-room, simply because it is a dark room, very frequently becomes the receptacle of everything which may happen to come in the way or appear obnoxious in other parts of the atelier. Old boxes full of straw, acid dishes containing old plates and giving off disagreeable fumes, which of themselves produce fog, a lot of empty hottles scattered around on the floor and shelves, and a quart or two of dust and dirt in each corner, are not unfrequently met with. You might spend thousands of dollars in the purchase of fine furniture, instruments, and apparatus, and yet, after all that, you will never succeed in producing anything above mediocrity, unless some care and attention be given to this particular department. If some of those photographers whose artistic (?) productions have never taken a prize medal at a foreign exposition could have occasion to compare their dark-room with that of some first-class workman who has received a grand medal of merit at Paris, London, or Vienna, they would find upon inspection and inquiry that their success is not to be attributed to the use of some particular brand of collodion, or some lately-discovered developing agent. Success is not likely to crown the efforts of any man who takes and reads no literature pertaining to his profession, and who shuts himself up in the quiet seclusion of his own dingy gallery, with its hushels of dirt, and imagines himself the fountain-head of all photographic information. Not many months ago, the writer of this article met one of those peculiar kind of photogaphers last alluded to above, who had voluntarily reduced the price of photographs from three dollars per dozen to one dollar and fifty cents, and even less, rather than miss a trade, and that, too, in the absence of all opposition; who, when receiving fifty cents from a customer for eighteen tints, remarked that he would not fear Sarony, Bogardus, or Mora, if they were to bring their fine establishments and set up in opposition to him. Such egotistical, homhastic assertions from one so low in the scale of photographic intelligence, grates upon the ear of the refined, like the haying of the illustrious sire of the mule.

For many years I followed the rules laid down by my instructor in regard to the arrangement of the dark-room, one of which was to keep the cyanide, hypo, sulphuret, and all the different acids in the dark-room within easy reach of the

* Practical Photographer.

operator; but after considerable study and sad experience I came to the conclusion that there was undoubtedly something wrong. A general overhauling of matters and things revealed the fact that acid dishes, cyanide, hyposulphite of soda, sulphuret of potassium, and dirt, were not calculated to be valuable acquisitions to a properly-arranged dark-room. When the above articles are present in large quantities, they work serious mischief. Hard, chalky negatives, with no details in either the lights or shadows, is the result of keeping cyanide and sulphuret where their fumes can gain access to the plate before exposure and development. Fog is produced by dirty plates, dirty fingers, fumes of cyanide, sulphuret, turpentine, and ammonia in the dark-room. Never attempt to silver a red fume in the same room where plates are coated, sensitised, and developed, for the fumes of ammonia, being alkaline, will produce fog as certain as the sun rises in the east. If the articles above mentioned are entirely prevented from gaining access to the dark-room, and that place be kept neat and clean (for it should be wiped all over inside with a wet cloth every evening), and the bath, collodion, and developer be made of pure materials and the proper strength and thoroughly harmonized, there will be no more danger of fog than there is of a collision of the earth and the sun.

I would recommend every artist to use albumenized glass, and even though he may not be an artist in the strict sense of the term, yet good negative glass, well albumenized, and pure materials, with a fair share of brains, will make a very good photographer, which is almost equivalent to being an artist. No man ever achieved success in the photographic business without a good deal of care, forethought, and painstaking exertion to equal or surpass the best work made by his competitors.

Some writers commit a serious oversight in giving directions for securing rapid-working silver solutions. They give a formula with all the different proportions of water, silver, nitrate of baryta, and acid, but not often do they give directions for harmonizing the collodion bath and developer. It is a well-established fact that if no harmony exists between the solutions, then nothing but a dubious lot of photographic apologies for pictures will be the result. It is another well-known fact among experienced workmen that if the bath is acid, the collodion must also be very slightly acid in order to preserve harmony and prevent streaks in the direction of the dip. If the one is acid and the other alkaline, the moment they are brought in contact with each other an effervescence ensues, which is fatal to clean manipulation, for lines, marks, splotches, and veilings of one kind and another will be the result. If the collodion is very red, it indicates acidity, which is caused sometimes from the ether, which often contains acid, and sometimes from the cotton, which has been imperfectly washed; and often, yea, very often, from the decomposition of the iodides used in salting. If the collodion contains an excess of iodide of potassium, it will work quick when two or three days old, but will soon begin to lose its good qualities and will turn very red, in which condition it is wholly unfit for the production of good negatives. The red colour can be removed from the collodion by dropping a small piece of cyanide into it; but I do not approve of that method, for the reason that it renders the film very tender. The best thing I ever found for removing the red colour from collodion is a few drops of spirits of ammonia; a small piece of unslacked lime will have the same effect, but the collodion must be filtered again before using.

When a bath is tested with litmus paper and found to be quite neutral, it is then in its most sensitive condition, and must be used with a collodion containing very little or no colour, if the full effect of rapidity, roundness, and brilliancy be desired. No quick work or instantaneous views can be made with old red collodion and a bath containing a quantity of acid; at least, the writer has tried all the different ways, and came to the conclusion years ago that the nearer neutral the bath and collodion could be kept, without being alkaline, the quicker and better were the results. It is of little use to take an old bath which has been crowded full of acid

in the vain endeavour to get rid of fogging, and neutralize the same, thinking to make a rapid working bath, for the nearer neutral it is, the less organic matter it must contain in order to work clean and clear in the shadows. The best plan is to weaken an old bath until it indicates about ten grains to the ounce by the hydrometer, which is best done by pouring the bath into distilled water (having previously neutralized the bath), and filtering to get rid of the excess of iodide, and after sunning for at least a week it may be again filtered and placed in an evaporating dish and boiled down to almost dryness, when it can be taken off and cooled and reduced to forty grains to the ounce, when you will find, by the addition of one drop of glacial acetic acid to the quart of solution, that it will work good enough for anybody, unless the bath previously contained cyanide, in which event it will never work satisfactory. If the bath is acid the collodion should be slightly red; if neutral, then the collodion must be clear. I may say the best results are always obtained with a neutral bath and a clear or almost colourless collodion.

Streaks in the direction of the dip are caused by a want of harmony between the collodion and bath. A drop or two of tincture of iodide added to the collodion will generally effect a cure; but if it be of a faint orange colour, and the bath indicates acidity, then it is better to neutralize and sun the bath, for it is a settled fact that old King Sol is the best doctor a photographer can employ in cases of sick baths. It is always best to have a number of baths for different occasions, so that if one gives down on a rush of business you have another in readiness, and thus be in a position to accommodate any reasonable number of customers without any serious trouble to yourself or annoyance to the sitter.

There is one more serious fault with many, and that is they spend the earnings of the room in horse-trading, which should properly be used in buying food for the cow that gave the milk; but instead of that they have but one bath, which is used day after day for negatives and ferrotypes alike, not stopping to remember that the conditions which favour the production of a good ferrotype are wholly unsuited for the production of negatives. While a ferrotype bath may, and in fact must, be slightly acid, a negative bath, when made of pure materials, seldom requires the addition of a restraining acid. Any photographer who aims to produce good work will never attempt to make use of but one bath only, but will provide himself with four—two for negatives and two for ferrotypes, and will mix two different kinds of developers to suit the different kinds of work in hand.

In testing old baths to ascertain the amount of silver they contain, the chances are in favour of the operator being misled by the indications on the scale of the hydrometer. Every photographer who has given the subject a thought must know that every plate which is dipped in the bath leaves behind a certain amount of chemical compound which, though not so heavy as silver, yet contains sufficient density to partly compensate for the loss of specific gravity sustained by the bath. Whenever a collodionized plate is immersed in a solution of nitrate of silver, a double decomposition ensues, wherein bromo-iodide of silver is formed in the body of the collodion film, and the bases of the salts used in sensitising the collodion are liberated. The theory is this: the iodine and bromine contained in the iodides and bromides used in salting the collodion having a greater affinity for silver than for the base with which they were combined, desert their first love and unite with the silver, forming bromo-iodide of silver: the gas liberated by such decomposition immediately uniting with the bases before liberated by parting with their iodine and bromine, forming nitrates of the bases, whatever they may be, and these nitrates, being soluble in a solution of nitrate of silver, are immediately dissolved and taken up by the remaining silver, thus helping to maintain the specific gravity of the bath solution, thus deceiving the photographer, who thinks his

bath rich in silver, when in reality it may be one-third nitrate of cadmium, ammonium, or potassium, or a combination of all these, depending entirely upon the salts used in the collodion.

A curious phenomenon sometimes occurs when there is a want of harmony between the collodion and the bath, in the shape of well-defined streaks which extend from that edge of the plate which first entered the bath, to the opposite edge, growing gradually weaker until they mingle together, forming a perfect veil over the entire edge of the plate which was last covered by the silver solution. The same effect can be produced on a cool day by breathing on the surface of the plate and wiping with a brush before the moisture has had time to evaporate. But if satisfied that it is the want of harmony which produces them (for you can settle that question by first breathing upon the plate and drawing the dusting-brush from one end to the other, and afterwards dipping the plate so that the long side shall strike the solution first), it will be best to test the bath for acidity, and if found to contain enough acid, the streaks and veiling can be removed by the addition of a few drops of tincture of iodine, which you can make by dissolving eight grains of iodine crystals in one ounce of Atwood's patent alcohol. I cannot too strongly impress upon the minds of those photographers who are troubled with fog of different kinds, lines, marks, dots, pinholes, comets, &c., the importance of establishing a rule to wash and clean up the dark room every evening after the day's work is done, for fine work cannot be done in a room where everything is covered an inch deep with dust and dirt. After a thorough renovation has been effected, which would be a very heavy task in some rooms, it need not require more than fifteen minutes of an evening to clean everything about the dark-room, which legitimately belongs there, and the small amount of trouble and expense incurred will be the means of causing you to go home Saturday evenings with a lighter heart and heavier pocket than you would if small matters like the above had not been attended to properly.

PHOSPHORESCENT POWDERS.

A RECENT English patent, says the *Scientific American*, is to obtain and to utilize at night time the light taken or absorbed during the day time from direct or indirect sunlight, or from an artificial light, either by employing phosphorescent powders simply after exposure, or by augmenting their brilliancy by means of electricity. The composition and manufacture of the luminous products and their applications without the use of electricity, is thus described: 100 parts by weight of a carbonate of lime and phosphate of lime, produced by the calcination of sea shells, and especially those of the genus *Tridacna* and the cuttle fish bone, are to be intimately mixed with 100 parts by weight of lime rendered chemically pure by calcination, and add 25 parts by weight of calcined sea salt; from 25 to 50 per cent. of the whole mass of sulphur, which incorporate therewith by the process of sublimation; and from 3 to 7 per cent. of colouring matter in the form of powder composed of monosulphure of calcium, barium, strontium, uranium, magnesium, aluminum, or other minerals or substance producing the same physical appearances—i. e., which, after having been impregnated with light, becomes luminous in the dark. After having mixed these five ingredients intimately, the composition obtained is ready for use according to different methods of application. In certain cases, and more especially for augmenting the intensity and the duration of the luminous effect of the composition, the patentees add a sixth ingredient in the form of phosphorus reduced into powder, which is obtained from seaweed by the well-known process of calcination. As to proportion, it is found that the phosphorus contained in a quantity of seaweed, repre-

senting 25 per cent. of the weight of the composition formed by the five above-named ingredients, gives very good results.

The phosphorescent powder thus obtained, and reduced into paste by the addition of a sufficient quantity of varnish, such as copal, may serve with advantage for illuminating a great number of objects—e. g., buoys, sea compasses, barometers, street plates, sign boards, and other similar objects—by arranging it in more or less thick coatings upon a plate of metal, wood, glass, or other material, covered by a transparent glass; this powder may also be employed for theatrical scenery or pictures, artificial flowers, and other similar articles by the application of one or more coatings of the powder incorporated in the varnish, or else by varnishing previously these objects and by sprinkling the dry powder upon the varnish still damp, and, in this case, the covering piece made of glass or other transparent material may be suppressed.

These powders are also employed for manufacturing solid objects generally made of cellulose, paper paste, papier-mache, artificial ivory (sometimes called coralline), and other materials of a similar nature, by sprinkling the surface of these objects, or only certain parts of the surface (still damp or moist) which are usually exposed to light, and by compression in moulds or otherwise in order to incorporate definitely the phosphorescent powders into the surfaces. The amount of powder applied should not exceed the thickness of a thin sheet of cardboard; it may be employed either for coating the whole surface or certain fractions thereof, so as to produce various designs, inscriptions, or effects. For this application, various powders are also applied, which contain different colouring matters, so as to produce effects of various colours.

The dry phosphorescent powders are also converted into translucent flexible sheets of unlimited length, thickness, and width, by mixing them with about 80 per cent. of their weight of ether and collodion in equal parts in a close vessel, and rolling the product into sheets, with which any object may be covered which is intended to be luminous in the dark.

The phosphorescent powders may also be intimately mixed with stearine, paraffine, rectified glue, isinglass, liquid silic, or other transparent solid matter, in the proportion of from 20 to 30 per cent. of the former with from 50 to 80 per cent. of either of these substances, and this mass is then reduced into sheets of variable length, width, and thickness, according to their intended applications. A luminous glass is also manufactured by means of the above-mentioned phosphorescent powders by mixing the same in glass in a fused state in the proportions of from 5 to 20 per cent. of the mass of glass. After the composition has been puddled or mixed, it is converted into different articles, according to the ordinary processes; or after the manufacture of an object still warm and plastic made of ordinary glass it is sprinkled with the powders, which latter are then incorporated into the surface of the article by pressure exerted in the mould, or in any other suitable way.

It has been observed after various trials, that the passage of an electric current through the different compositions augments their luminous properties or brilliancy to a great extent; this peculiarity is intended to be utilized in various applications too numerous to describe, but of which buoys form a good example. The current of electricity is furnished by plates of zinc and copper mounted on the buoy itself, when the latter is used at sea; but in rivers and fresh water inlets the battery will be carried in the interior of the buoy. To secure the full effect, from 10 to 20 per cent. of fine zinc, copper, or antimony dust is added to the phosphorescent powder above described. The patentees, Peiffer, MacCarty, and De Sagan, have devised a special form of buoy, which they claim is their invention, in company with the various applications above described.

CLUB PORTRAITS.

WHEN business is dull, expedients of all kinds are tried to give it an impetus; and the establishment of portrait clubs has found favour with some photographers. Runour tells of cases in which working such clubs has proved not simply an aid to flagging business, but has actually issued in very lucrative results. The modes of forming and working such clubs will vary with circumstances, but we may briefly indicate the modes of proceeding adopted, as we have been informed in some cases.

The first step to be taken consists in finding a community of persons bound together, or, at least, meeting together, on some common ground. In some cases it is a large workshop or business establishment in which many "hands" are employed; sometimes a school or denominational body: no matter what the bond of union, so long as they meet together and can form compacts for any definite purpose. Next it is necessary to find some influential or representative person in connection with the community in question: if a workshop, then the foreman is a suitable person; if a society or association of any kind, then the secretary. To such representative person overtures should be made, stating the object, and offering some inducement to secure his services in making a contract. A good specimen of this kind of portrait should be ready, and it should be offered to the community at a much lower price than would be charged for such portraits singly. The inducements offered to the foreman, secretary, &c., to undertake the introduction of the idea may take the form of a percentage on the total receipts, or one or more gratuitous portraits of himself or members of his family. It is important to offer tempting terms to this representative, as upon his action depends the formation of the club; and, when formed, he generally undertakes the duty of collecting the money in weekly instalments until the full amount is collected.

We have been presuming that the photographer has his studio handy and easy of access for the members of the club. But that is not always necessary. We have heard of cases where the club portraitist establishes his position, and works out his project far away from his studio; and, having established his club, and secured the names of a number of members, he makes arrangements with the nearest suitable photographer to take the negatives of a given size and style at a fixed rate agreed upon. The negatives are probably card or cabinet negatives suitable for making enlargements, of which the club portraits most frequently consist. In some cases they are enlargements by camera printing on collodion; the film being generally transferred to paper, and cheaply coloured, and placed in

a showy frame, make an effective picture, which can be supplied at a cheap rate.

In a recent issue of the circular "Notes," issued by the Autotype Company, some information is given, and some offers are made to photographers generally which, whilst partaking of the nature of an advertisement, and hence not usually suitable for this part of our column, may prove sufficiently interesting to our readers to justify us quoting some portions. The article, entitled "Portraiture for the Million," says:—

"It is notorious that fresh ground has been broken and successfully cultivated by at least one enterprising firm which has appealed to the million, by offering an attractive article at a cheap rate, and organizing the 'Club Portrait' system in a manner to make payment come easy to the purchaser and sure to the producer. Coloured transfer enlargements hastily coloured and enclosed in cheap showy frames cannot be considered as 'high art,' but they have satisfactorily answered to the demand. They have contented the purchasers, they have enriched the producers, and have thus legitimately fulfilled the conditions of successful trade. If the producer, in addition to the reward of the trader, claimed the renown of the artist, the claim must provoke derision, but, looked at simply as 'business,' the transaction is creditable in itself and deserving of success, as pioneering, however rudely, a new and immense field of work. It shows how the artisan and labourer, the small shopkeeper and the employé, desire to see the features of himself and his family limned by the photographic pencil, coloured, more or less, like life, and in dimensions large enough for framing as a 'joy for ever' on his walls: and how the attainment of this luxury may be brought within easy reach.

"Many photographers object to collodion transfers as teaboardy and trashy productions, unworthy of notice, and have demanded of the Company if Autotype cannot supply a more satisfactory class of portrait. The question has not applied merely to the club portrait, but also in reference to a fairly-painted life-sized head and bust, framed in gold, that might be retailed at four guineas as a family portrait, to content the desires of people who can afford such a price, and yield to the producer of the original negative a respectable profit.

"It is very well known that the 'Club Portrait' is a 10 inch by 8 inch collodion transfer enlargement, coloured in oils, and put in a washable gilt frame, about 14 inches by 12 inches rebate, with a bronze mount, oval or dome cut to 9½ inches by 7¼ inches sight size. This is offered complete, and a dozen cartes thrown in, for the sum of thirty shillings. From this total five shillings has to be allowed as commission to the 'traveller,' who enlists the members of the clubs and collects the weekly shillings. Thus a club of thirty members paying but one shilling each per week would require thirty weeks to complete the transaction. Priority of delivery is determined by lot, and with half-a-dozen clubs going, six portraits would be delivered weekly. It may be readily understood that given a portrait which attracts the million, an energetic firm with capital at command, and good organization in many centres of industry at the same time, would be able to do an enormous and profitable trade. Such a firm has the merit of opening a new mine of wealth, but in the nature of things the enterprise must be competitive. A glass house opened in a town for club portraits principally will touch all other forms of the business attainable, will tend to lower prices all round, and the local photographer must prove himself very energetic not to feel adversely the new influence at work.

"The Autotype Company has hitherto aimed exclusively at high-class work, and has, indeed, been sufficiently exercised to meet, without unreasonable delay, the rapid development of its business; but having increased its building accommodation, perfected its plant, utilized artificial light on a large scale, and trained to complete

efficiency a numerous staff, is now able to attend to the wishes of those numerous clients who are desirous of offering a respectably-framed portrait enlargement at the modest figure that will suit the means of the many.

"Experiments have been for some time in progress to produce something new in cheap portraits, and to colour a picture in oils on a carbon base in such a manner that the resemblance should not be injured, nor the general effect staring and vulgar. The artistic part of the business in a very low-priced enlargement, coloured in oils, is the most dangerous. Inevitably such pictures, to pay, must be produced wholesale and rapidly, and photographers know very well how easy it is to spoil a decent enlargement with the brush.

"Rapid colouring without loss of likeness and without vulgarity has been aimed at, and, by a special autotype method, has, it is thought, been secured, so that with instructions as to colour of hair, eyes, and complexion, it will be almost impossible to fail in the likeness. Each portrait will pass through the hands of our Mr. Joseph Wake for final touching, and if the finished picture is a trifle more costly than the eolodion transfers in the market, it is intended that it shall be distinctly worth more money.

"The Autotype Company can have nothing to do with any club system. It will produce and supply to its customers from their negatives two distinct portraits, of a certain fashion and fixed price, likely to suit the classes for whom they are intended. Each photographer can decide for himself how best to push their sale in his own district. In towns where the artisan class predominate the club system of weekly payments has distinct advantages; but given the right article to attract the working man's money, the local photographer is in the best position to understand the local conditions of success.

"In furtherance of the object in view, the Company undertakes to supply:—

"First. An Autotype 'Club Portrait,' eight size, 12in. by 10in., head and bust only, full background, fairly coloured in oils, and framed in an effective washable glazed gilt frame, with a bronze mount, cut either oval or dome. The enlargement will be made from negatives only, and the price will be nett eighteen shillings. Copies of positives or Daguerreotypes will not be undertaken.

"Second. An Autotype 'Family Portrait' from negative, eight size, 23in. by 17in., head and bust only, full background, carefully finished in oils, by the Company's special method, and framed in an elegant gold frame. The price will be two guineas, and the retail value fairly double that amount. Copies of paper pictures, &c., will be undertaken for the 'Family Portrait' for one guinea extra.

"The photographer, in cultivating portraiture for the million, must bear in mind the old adage of small profits and quick (or large) returns. With the competition existing in club portraits the usual rate of profit cannot be expected; this branch should be regarded as additional to the regular trade. The expense of carriage must be minimised by arranging for delivery of (say) six portraits at one time. With a larger, and it is hoped better, picture than eolodion transfers, a higher price can be got; certainly with a dozen cartes added they should be worth at least thirty-five shillings. Prices vary according to circumstances and locality, and no hard and fast rule can be laid down."

The subject of club portraiture is essentially a commercial one, and many of our readers who are keenly alive to commercial interests probably know more on the subject than any journal can teach them; but to many others the subject will be new; as it affects their trade it cannot fail to interest them. We need no other excuse, therefore, for calling attention to the plan and its modes of working.

FRENCH CORRESPONDENCE.

M. LEON VIDAL ON PHOTOGRAPHY BY THE ELECTRIC LIGHT—ANNOUNCEMENT OF, AND EXPERIMENTS WITH A NEW RAPID PROCESS—GERMEUIL-BONNAUD PROCESS FOR PHOTOGRAPHING IN NATURAL COLOURS.

M. Leon Vidal on Photography by the Electric Light.—When I wrote the article entitled "Photography by the Electric Light in a French Court of Justice," I had not the slightest intention of putting my honourable colleague on his defence. In the first place, I had not the right to do so; and in the next place I have said nothing but what is scrupulously exact. My duty was to give a statement of facts, without taking account of what was the opinion of my fellow-worker in his capacity of Editor of the *Moniteur de la Photographie*, for I think I am right in believing that the PHOTOGRAPHIC NEWS would have no business to interfere in the management of another journal. A description of facts which is simply true ought never to become a subject of controversy. But while excusing myself to my readers for continuing a personal discussion, which I am compelled to do, having the right of reply, I would beg my honourable colleague to listen for a short while to the arguments which I advance in the same hospitable columns that he has selected for putting forward his own views. He confesses at the outset that he was in ignorance of any dispute on the subject of taking photographs by the electric light. This is at once an acknowledgment of my being in the right in mentioning the subject, since my aim is to make the readers of the PHOTOGRAPHIC NEWS acquainted with all that takes place here. I was the first to speak of the photographic operations carried on with the electric light, and to describe the fêtes—before the one at the opera house—to which they have given occasion; it was, therefore, nothing but just that I should go on to give an account of the events which followed, without any other considerations than those which influenced my vocations as a conscientious correspondent. To have ignored the question altogether would have been futile. Shortly, but precisely stated, here it is. The Editor of the *Moniteur de la Photographie* wrote an article in which he maintained that the apparatus and fittings used for the electric light at the opera fête were not protected by patent. M. Liebert protested against this statement. These facts I stated in your journal, of which I am a correspondent, and, in face of an action commenced in a court of law, I warned photographers against running the risk of being themselves subject to a similar inconvenience by introducing the Vander Weyde system before a competent decision as to the legal position of the patent rights had been arrived at. Now what could be more correct, or less reprehensible, than this? My honourable colleague excuses himself by saying that he published his account strictly according to the information that he received. Is it my fault if this information be erroneous or incomplete? I notice, with pleasure, his statement; I cannot, however, pass over in silence the censure which is implied—the more so, that the readers of the PHOTOGRAPHIC NEWS will scarcely care to consult the back numbers of that journal to read over again my letter, published on the 27th of June, and sent off from here on the 23rd. The rebuke to which I have laid myself open is, that I have accused my colleague of not having published M. Liebert's letter. The fact is, I merely remarked that such a letter had been sent off, and this I knew for certain, inasmuch as a similar letter, together with a request that it might be inserted, had been forwarded to the other technical journals, such as the *Revue Photographique*, on whose staff I have the honour of being a member. It never could have entered my head to accuse my colleague of such remissness, for the very good reason that the next number of the *Moniteur de la Photographie* after the date of that letter only appeared on the 1st of July. Had

I done so, I should have accomplished the feat of giving an account of an event before it had happened. If I had the power of proclaiming the news of an occurrence a week in advance of its taking place, I should be the most astonishing and most highly sought after correspondent of the entire universe. I cannot possibly allow myself to be supposed to possess an extraordinary faculty which I have, unfortunately for me, not the slightest pretensions to possess. I am not less in perplexity as to another little stricture that is passed on me. My honourable colleague complains that I did not send him a line on the subject of the action at law before I sent an account of it to you. Much as I have ransacked my memory, I find no precedent for a correspondent consulting his colleagues as to the nature of the news which he is going to publish. If all journalists were subject to restraints of that kind, I do not see how they would be able to fulfil their duties; working night and day would not be sufficient for them. Besides, this precaution, even if I had had recourse to it, would have been useless, since M. Leon Vidal confesses that his letters are lost in the post, and that in his case the post is so irregular as to deliver his copy of the PHOTOGRAPHIC NEWS more than a week after date. I content myself, therefore, by thanking my honourable colleague for the explanation he has been so good as to give, and to beg him to accept in good part my regrets for having vexed him unintentionally, at the same time expressing my sincere wish that his postman may for the future be more regular. If he wants it, I will give him all the assistance in my power, in a sincere spirit of good fellowship, to remedy this defect. What should we poor newspaper scribblers do if all our journals and our letters, like the dragons in one of the pieces of Offenbach, were always to arrive too late?

Notification and Trial of a New Rapid Process.—Great excitement has been caused during the last few days by the announcement of an instantaneous process which is to surpass all other processes yet known. It was stated in the *Petit Journal* that a foreign chemist had arrived in Paris with a method of his own invention, by which he was able to take a negative in two seconds under a cloudy sky. This was a piece of unexpected good fortune. "No more headaches," it was said; "the experiments already made have given most astounding results. In the open air the rapidity of the process is so great that horses can be photographed in full trot, and panoramic views can be taken from a balloon." I have quoted the paragraph word for word. Naturally, my curiosity, as well as that of many other photographers, was vividly aroused by this advertisement, which at the first reading seemed calculated to take one's breath away; and I went at once, in accordance with my duty as a loyal reporter, to obtain more precise information. It did not take me long to learn, on excellent authority, that some experiments had already been made by the newly-arrived benefactor of photography in several of the studios of the city. But it appears that it had very quickly been found necessary to put a damper on the strings of his too brilliant instrument. It was more than exaggeration, for there is some doubt whether the process be even workable; at any rate, it is generally agreed that the rapidity obtained is by no means extraordinary, and that the results are far from coming up to the standard announced by the *Petit Journal*. It must, however, be remembered that a political paper can scarcely be held responsible for its photographic news, published, apparently, in a fit of enthusiasm at a fever heat. We may, I think, say once more, with your great poet, "Much ado about nothing."

The Germeuil-Bonnaud Process for Photographing in Natural Colours.—On several occasions I have brought to the notice of the readers of the PHOTOGRAPHIC NEWS the process of M. Germeuil-Bonnaud for taking coloured photographs, and I also stated that a company for working the process had been formed at Paris. The inventor, however, has not been able to approve the provisional statutes of the company, on account of its being found impossible to

introduce some modifications that he desired, and he is therefore now at liberty to work or distribute licences for working his process as may seem best to himself. He has already sold his patent rights in America. In France, several photographers have seized the opportunity to introduce the process into their own laboratories. I am also glad to be able to inform you that it will soon be available in your own country; an agent of M. Germeuil-Bonnaud has already left for England, and will have full powers for disposing of the licence to work the process there.

K. VERSNAEYEN.

GUP.

"AND what, in the name of gelatino-bromide and artificial lighting, may 'gup' be supposed to mean?" I hear a chorus of those who have never either read Miss Florence Marryat, or luxuriated in the pleasures and pains of Anglo-Indian society, reiterating all round me. "Is it a patent combustible nightlight which burns for ever, and enables us to photograph the details of a shadow in a fraction of a second for a fraction of a farthing? or is it a strictly protected innovation in dry-plate work which we have all been innocently making use of for the last three years? No; 'gup' is none of these things. It is simply an Anglo-Indian abbreviation for 'gossip,' and for facility of pronunciation and extreme lucidity is about as satisfactory an expression as the abode of rajahs and of Messrs. Bourne and Shepherd has as yet contrived to produce.

Moreover, 'gup' is exactly applicable to the present lubrications. "It expresses what we mean, sirs," as Mr. Terry says in *Little Doctor Faust*, and is obviously a happier title than the "occasional memoranda upon contemporary events of passing interest," or any other such rigmarole that requires a gargantuan mouth to swallow it even piecemeal. Brevity is the soul of wit, my masters, and if the audience gathered to listen to the judicial utterances that emanate from the bench of the New s cannot appreciate the terseness, and, my modesty compels me to add, the vigour, of Chief-Justice "Kaleidoscope's" summing-up, they may go their ways and listen to the long-winded twaddle of Chief-Justice somebody else.

Occasionally writing social articles for a contemporary, and being some time since hard up for a suitable topic, I actually succeeded in evolving a column and a half out of the subject of gossip. One of my "points," I remember, was the distinction that ought to be drawn between gossip, and its ugly half-brother, scandal. I risk the imputation of bad taste in quoting myself, for a reason which I trust my readers will approve. The paragraphic style in which this is written may, perhaps, remind some of other instances in which it is now being widely adopted. Paragraphs even have been, are, and will be the chosen tools of scandal. But in their perusal of the present column, my readers must cast aside all idea of scandal or malicious comment. I have nothing but "gup" to offer you, nothing but light and lightsome gossip upon "the daily round, the common task," of the photographic community at large.

Of course, if folks will persist in going astray, "Kaleidoscope" must follow their example, and shake up his bits of coloured glass into all sorts of distorted shapes, if only to show what an ugly aspect is the natural outcome of a want of harmony. Otherwise, I am of opinion that we shall all agree remarkably well. I am an amateur without the least professional bias; I am not by nature pugnacious; and I am a bit of an enthusiast as regards photography and photographic progress. With this category of virtues, I will now formally introduce to you myself under the name—and "a good name too," isn't it?—of "Kaleidoscope." Beyond this, I shall take the liberty of remaining a photographic Junius, Historicus, Bernal

Osborn, or any other distinguished temporary incog. to whom my polite readers may think fit to compare me.

That was a pathetic letter from Mr Bradforde in last week's NEWS, respecting "bogus" employers; and, in one sense, it was a telling argument in favour of that good institution, the Photographers' Benevolent Association. At the same time, I can't help thinking, in an amateur sort of way, that the Association is of more use to the drones in the photographic hive than to such capable "workers" as Mr. Bradforde.

The above notwithstanding, "Kaleidoscope" will have half-a-sovereign ready if—and I am sure Mr. Harland will thank him for the proviso—nineteen others can be found to make up a "PHOTOGRAPHIC NEWS Subscription" of £10 to the funds of the P.B.A.

I don't feel satisfied that Mr. Bardforde, armed with his letters from his anything but gay deceiver, would be guilty of libel in publishing that—ahem! individual's name; but, doubtless, Mr. Bardforde has satisfied himself on this not unimportant point.

Hurroo! Begorra! Erin mavourneen, slan lath go bragh! Ceade mille failtha (*Anglice*—a hundred thousand welcomes) to the Photographic Society of Ould Ireland, with its broth of a president, whom "Kaleidoscope" doesn't happen to know, but respects and esteems all the same.

In reference to the wide and somewhat prolix discussion about adiactinic media ("Kaleidoscope" naturally feels interested in coloured glass), I have seen some orange paper which, steeped in boiled oil, is (so the extremely "rapid" firm of 38, Great Queen Street, tells me) a perfect protection, even for instantaneous gelatine plates, against daylight. It has the additional advantages of giving ample light, and being delightfully cheap.

I want to know when tourist photographers are going to bid farewell at any rate to the bulk of the glass which most of them are forced to carry about with them. Herr Warnerke's tissue is convenient, but it is dearer than the glass which it discards. Mr. Woodbury's plan of transfer is a neat one, but necessitates coating a batch of plates for each day's exposure. The Rev. H. Palmer has made progress with his gelatine films, and Mr. Ferrier has done good work in the same direction. But all this is hardly conclusive. Is it not possible to make a removable sensitive film by first rubbing a glass plate with French chalk, next coating it with plain collodion, then with chrome-almud gelatine (as in Mr. Henry Cooper's substratum), and lastly, with collodion emulsion? Unless I am mistaken, this would be an improvement on Mr. Ferrier's plan, and I regret that time and opportunity are not allowed me to prove or disprove my theory. Perhaps one of my readers will lend a hand and some brains to put this little matter straight.

Can't some intelligent artist make an exhibition instantaneous picture of the crowd thronging to a morning performance of a popular piece? The departure of the Comédie Française has removed, perhaps, the best of all opportunities; but abundance of good ones still remain. A group of old women gossiping over their tea, too, would make a capital picture; it might be called "Gup," and be dedicated to
KALEIDOSCOPE.

APPARATUS EMPLOYED IN THE GELATINO-BROMIDE PROCESS.

BY A. J. JARMAN.

ALREADY I have received a large number of letters asking if I supply plates and emulsion, and what kind of drying-box I use. At present I am not in a position to undertake the manufacture of plates on a large scale, my main

object being to give all the necessary instruction, as far as I am able, so that photographers may prepare their own plates; and I sincerely hope that by following every description that they will succeed as well as I have done.

Fig. 1 gives a sectional view of the drying-box. A is a zinc tube four inches in diameter; B is a zinc tube two inches diameter; C is a small gas jet that burns in the bottom of the tube B, and warms the said tube, thereby causing the air that passes up A to become slightly warmed, and passes over the first shelf of plates, and so on to the bottom of the box, and passes out by the tube B. It will be seen that the air *must* pass through the box before it can

Fig. 1.

Fig. 2.

supply the gas flame. If cold draught is required, light the top burner, D, and if required to dry spontaneously, then break up some quicklime, about the size of cracking nuts, and three parts fill the two trays shown in sketch; close the door, and in about two days the whole box of plates are nicely dried.

Fig. 2 gives a sectional view of my emulsion kettle. The sketch will explain itself. A is the kettle, B the earthen jar, C the bottle containing the emulsion, D the thermometer, E gas jet, F three-legged iron stand, G is a conical lid, so that a large-necked bottle can be used for the emulsion.

Fig. 3.

rest on the top of a Silber paraffin burner; three sides are fitted with deep ruby glass, six inches by four inches; the back part is fitted with a door; the chimney is that of an ordinary magic lantern, which, by the elbow, stops the light from striking the ceiling of the room.

I sincerely hope the above sketches and description I

have given may prove themselves of value to all photographers who have been seeking practical information for working the gelatino-bromide process.

SIMPLIFICATION OF THE METHOD OF PREPARING GELATINE EMULSION.

BY PHOTO-CHEMICUS.

A DEBT of gratitude is certainly due to your correspondent Mr. Jarman, for the liberal manner in which he has stopped a gap for the benefit of his professional brethren, by his most lucid explanation of the process of preparing and working gelatine emulsion plates. His paper is exactly the right thing at the right time; and, so far from complaining that he has repeated a "thrice told tale," I feel sure that your readers will heartily welcome *any*—even the most trivial—details in connection with a process which, having slumbered for so many years since its invention by Dr. Maddox, has now come suddenly to the front in a manner which threatens to revolutionize the whole practice of photography.

I sincerely trust that every worker in this department will freely add their experiences to those of Mr. Jarman, as they may fully depend that no information they have gained by practice can be too trivial to interest their fellow-workers.

With this feeling, I am induced to add my mite to the common stock, my special object now, being to simplify Mr. Jarman's process for the benefit of brother-amateurs.

The plan I propose involves no outlay for apparatus of any kind, and enables us to carry the whole process nearly through in daylight. It is as follows:—Having prepared, set, cut up, and washed the emulsion (the latter by Wratten and Wainwright's method), I melt it, and pour it into a common stoneware ink bottle, cork this down, and, for still greater security, tie the cork over with leather. I then immerse this in an ordinary saucepan containing water from 90° to 100°. I then bring this out of the dark room into one in which it may be constantly under my observation, and, by means of the smallest possible light from a Bunsen burner (and it is astonishing how little heat is required), keep it for three, four, or five days at the required temperature. Where gas is not available, a night-light, or perhaps even two, under the saucepan answer equally well. Test the temperature occasionally, taking precautions that the heat shall not rise much above 100°, and fill up, as evaporation occurs, with warm water.

When digested sufficiently long, take the jar back into the dark room, and it is ready for use. The jar may be opened at any time, and a plate coated, exposed, and developed, as an experiment. Of course the process may be reversed, and the washing, &c., done after the digestion; but I prefer the former plan.

The question is often asked why the effect of long digestion should be to increase the sensitiveness of the emulsion. The reason appears to be that when first made it is probably a simple solution of gelatine, in which silver bromide is *mechanically* suspended, and that the effect of digestion at increased temperature is to create a *chemical* combination in which silver bromide is no longer the active agent, but a compound of the organic matter, bromine and silver—in fact, what may be called "organo-bromide of silver." Now as, in a general way, organic salts of metals are much more readily decomposed by chemical agents (light being a most powerful one) than inorganic, the silver salt so created is much more readily reduced than the stable silver bromide. Hence each day's digestion renders the solution more sensitive, because every hour is creating more of the triple combination, and (*theoretically*, at least) the most perfect emulsion would be that in which this combination had been carried to its utmost limit; but *practically* this point is not likely to be attained, as decomposition would probably occur before such limit was reached.

FLEXIBLE NEGATIVES.

BY A. W. TURNER.

THERE has long been wanting for many purposes in photography a reliable method of removing the negative film from the glass to an equally transparent, though flexible, support; and having, in the course of some experiments, discovered a simple method by which this result can be obtained, I hasten to make known to your readers, trusting that they will give it a trial to find as much satisfaction in its use as I do myself. Without further parley I will proceed to describe my mode of working.

I take an ordinary varnished and retouched negative, place it in a dish of cold water, and with it a piece of sheet gelatine about a quarter-inch smaller all round than the negative (a sample of which gelatine I enclose to the Editor). Allow this to soak a couple of minutes, until slightly limp; take both out of the water together, and squeeze in a similar manner to ordinary carbon prints, with a piece of india-rubber cloth over it to prevent injury to the gelatine. Now put the negative, with gelatine attached, into another dish containing methylated spirits for a few minutes, to absorb as much of the water from the gelatine as possible. Stand it in a plate-rack to drain, until it is surface dry, which will only take about five minutes or so; then coat with normal collodion, and stand up in a warm room till dry, which will be in the course of an hour or two, when, by gently raising the film with a penknife, it will entirely leave the glass, and you will have a flexible negative as transparent as when on the glass, which can be printed from either side.

I need hardly enlarge on the advantages of this class of negatives, and have only to remind photographers how they can be used for the single transfer carbon process without obtaining reversed images; they can be kept in books like ordinary paper prints, are easily cut, besides a host of other advantages too numerous to mention.

In addition, there is a great saving in expense, as the glass can be used over again as often as you like. Varnished negatives, however old, can be transferred by this means, except when they have been taken on albumenized glass; and even, these if they are only a few days old, are easily removed; but it appears from my experiments that old albumenized negatives become so attached to the glass by the coagulation of the albumen that they cannot be detached by this means; in fact, in one instance, the film actually split, one half coming off on the gelatine, and the other remaining on the glass. This is my experience on this point, but I should like to have some of the results obtained by others with albumenized glass. With other negatives I find the method work without the slightest defect, and, in proof, enclose a few flexible negatives to the Editor, one of which was taken at least five or six years ago.

I must confess I was rather surprised myself at the easy way in which the films can by this means be removed, and can only account for it by the fact that the gelatine when soaked in water expands so much that its contraction in drying is sufficiently strong to overcome the attraction of the collodion film to the glass, which, being in the slightest degree disturbed, of course leaves its original support. The methylated spirits I use to hasten the drying, and the collodion to prevent the gelatine curling up when it leaves the glass; without it the contracting power of the gelatine is so great that it drags the film from the glass before it is dry, and consequently spoils the negative.

I only intend this as a short record of the result of my experiments; and this being now my busiest time, I am forced for the present to lay aside; but any further information on the subject I shall be happy to give your readers, if required, and trust that they will at least give this method a trial.

THE WEATHER: GROANS FROM UNDER THE SKYLIGHT!

BY W. G. SHAW.

COMPLAINTS and grumblings seem to be the order of the day, or, rather, of the year. The drizzling rain and chilly atmosphere of July are perhaps enough to raise a sigh of anxiety even from a patient photographer. As the rain patters on the skylight, and sundry vessels are distributed upon the floor to catch the droppings of a leaky roof, it is little wonder that sitters are scarce and operators wanting situations plentiful.

Our worthy Editor, but a short time ago, alluded to the probability of experiments in artificial lighting being abandoned during the summer (?) months.

Under existing circumstances, photographers will no doubt feel more graciously disposed towards the proposed employment of a system which will enable them to work in a warm and comfortable apartment, instead of under the melancholy expanse of skylight revealing a leaden sky, and emitting sundry and divers unpleasant droppings.

It is an ill wind that blows nobody any good, and it appears as though vendors of rapid dry plates would reap a harvest during the present weather, if there are not too many of them in the market. It is evidently the process of the future, and before long every portraitist will have his own favourite brand. The difficulty to be overcome (if it can be overcome) is the tedious development of emulsion plates, which, after the rapidity of the ordinary process, is trying in the extreme when one is busy, while to let customers go away before developing is a risk somewhat formidable.

Undoubtedly, there is a charm in photographic art by which every true disciple of the camera is held spell-bound. The sentence relative to the late Mr. O. G. Rejlander in last week's News, "But he lived and died a poor man," contains a strangely bewitching pathos. Are there not many unknown ones, many whose picture contains real merit—though they could not be exhibited by the side of his—who have also felt the bitter pinch of poverty? Men with large ambition, good talent, but small capital. Unbusinesslike, it may be, but true artists, nevertheless. It has been said that good artists are muffs at business.

From time to time, trying seasons have thinned the ranks of photographers, and, judging from the number of studios and businesses being advertised, the present period promises to make a rare clearance of those who have grown weary of the smell of collodion. However grand a sentiment may be, one cannot live upon it: neither love for the camera nor "love in a cottage" will avail to satisfy hunger when the cupboard is empty; and as the profession will not suffer by a decrease of its followers, nor the public fail to receive sufficient photographic attention, we would not suggest one word of reproach upon those who contemplate turning their backs upon the studio.

Specially unfortunate, indeed, are our sea-side friends this year. Those who depend upon a good run from June to October are drawing long faces. What visitors are not kept at home by the depression of trade, or economy necessitated thereby, will scarcely be tempted to venture into "lodgings by the sea-side" in weather like this. The present is surely a time for legitimate photographic dodging (I don't mean questionable transactions), and fertile indeed must be the brain of the photographer who can invent some means to induce sitters to visit the studio.

Let us, however, take heart and hope that even yet, before "the harvest is past and the summer ended," some bright genial sunshine may cheer us into good spirits once more, and remembering (by this foretaste) the dreary days of November that may be in store, let us be more than usually careful against indulgence in spirits which are *not* good, either for our pockets or our brains.

PHOTOGRAPHING THE RACE HORSE IN MOTION.
The San Francisco *Morning Call*, publishing some comments from the East and from Europe on the photographic feat of Mr. Muybridge, says:—

The adage that a genius is never appreciated at home is fairly exemplified in the result of the instantaneous photographing of horses in motion, suggested by Governor Stanford and carried into practice by Muybridge. The idea was a grand one, not alone for its applicability to the purpose which first gave occasion for it, but as it could be made available in so many other ways to advance science and art. It settled questions in relation to the action of horses which had long been in dispute, and startled those who fancied they had an intimate acquaintance with the manner in which a horse handled his feet and legs at a fast trot and gallop.

Those who witnessed the method of accomplishing the object could not cavil at the correctness of it, and a written or verbal explanation to a man of intelligence was generally sufficient to convince him that the pictures were accurate. But the first which were printed, viz., one representation of Occident when trotting fast, was ridiculed by nearly every one, and a New York journal characterized it "as too absurd for belief or comment." That was taken when one fore foot was extended to the utmost point, at the instant it came in contact with the ground, and it looked more like the representation of a horse coming to a sudden stop than the usually accepted ideal of foot motion.

Artists who had made a study of the horse were unanimous in pronouncing it a humbug, though there was an inherent verification to the few who had closely scanned for years the positions of the limbs, and who had closely studied with a view of solving the problem of how to improve the action, in order that the animal might be enabled to go faster. When this picture was taken the machinery was in an imperfect state. Gov. Stanford inquired of Mr. Muybridge if he could photograph the horse in motion. The answer was, Not with the present instruments, but that he thought he might perfect them so as to do it. Several experiments were tried, and the most satisfactory one was a kind of clock-work arrangement, graded to the supposed speed of the horse. This required to be started as the horse came opposite the first camera by hand, and the synchronism between the human eye and hand was not exact enough to give an absolutely correct result. A happy thought—an inspiration, it might be termed—gave the cue to success.

When Governor Stanford struck the last spike which connected San Francisco and New York, the blow resounded over the bay in the booming of cannon simultaneously with the fall of the hammer, and every inhabitant of the city and surrounding country was aware that the long expectant hope was consummated. Upwards of eight hundred miles, across high and rugged mountains, athwart sterile plains and rich valleys interveued, but not even the two-hundredth part of a second marked the interval between the stroke and the report. Why not avail themselves of the agency of the subtle fluid which could thus annihilate space? Fortunately, there was a liberal spirit and abundant means to carry out the suggestion, and the best artisans of San Francisco and England were called upon to perfect the details. Assiduously Muybridge laboured. Whether in the frozen North or among the plantations of Central America, his thoughts were on the future. Could the magician, more potent than ever the wildest imagination pictured, be brought into service, or that which had proved such a boon in other pursuits be successfully evoked? Those who witnessed the operation on that bright June day at Palo Alto can answer that never was a more satisfactory demonstration. The trotter, after being "warmed up," as though he were to start in a race, came whirling by. There was a whizz as the sulky wheels pressed the wires which opened the cameras, and the whole series of twelve pictures were taken in less than the half of a second. Eagerly the small group scrutinized the piece of glass as it was lifted from the bath, in the tinted light which came through the yellow screens. There was the flying steed in every position, transferred with such delicate fidelity that there was a feeling of awe mixed with that of gratification at the marvellous exhibition. Necromancer never accomplished anything to compare with it. A still more arduous task was to give the stride of the race horse with the same perfection. The wheels could not be utilized to release the electrical current, and threads were stretched across, which would break as the animal swept against them. The velocity was greatly accelerated, and the rush was as swift as the flight of an eagle. The record was again on the glass, perfect, though the forms so grotesque that men who had owned and ran race horses for a quarter of a century were staggered at the incongruity—the difference between the real and the imaginary. Here was a new era. The beliefs of the past were

shattered, and new convictions to take the place of long-cherished, though ignorant opinions. Many things could now be explained, heretofore impenetrable, and injuries avoided which before were accepted as inevitable.

The *Call* then gives an account of the tokens of appreciation of his efforts and congratulations on their result received by Mr. Muybridge, not only from foreign correspondents, but from many Eastern gentlemen, and concludes as follows:—

The cartoons representing the fast gallop give a key to the breaking down of so many horses. In trotting, the body is supported by two feet at a time, one fore and one hind foot, carrying the animal along until the bound is made, or very nearly so, probably the hind foot a little later, in order to give the most force. This brings an equable strain and throws the work on both. In running, the hind feet, at one point of the stride, touch, but in the series of eleven pictures, only one shows them in this position. But while there may be a time when both of the fore feet are on the track at once, the cameras, twenty-seven inches apart, failed to record it, therefore the presumption is that one fore leg has to sustain the whole of the weight, animal and rider, while the body is moved along five feet. Just before the foot is elevated, and while it is yet on the ground, a perpendicular from it will strike back of the saddle. This adds to the weight the immense leverage which the head, neck, shoulders, and rider exert, owing to the centre of gravity being thrown so far forward of its support. While this foot is directly under the rider, the weight forces the ankle to the ground. From this it is evident that the tendons must have a terrible tension, and no wonder that the sheathing of them is ruptured.

Correspondence.

GAS-LIGHT PORTRAITURE.

SIR,—Through the application of gas to portraiture by Mr P. M. Laws, no doubt many photographers, with myself, are looking forward to the approach of winter with eager interest. Yea, in the face of such a summer (save the word!) is there not a hope that with Wigham's burner in our studios we might in some measure make up for past losses? But we must first "put our houses in order:" procure one of the large lamps, with all necessary adjuncts, as reflectors, &c. In your admirable article last month you say, "Of course reflectors play an important part in utilizing gas-light for purposes of portraiture, and Mr. Laws has adapted very simple but *efficient* reflectors." Judging from the softness and general beauty in the lighting of some of Mr. Laws' gas portraits, these reflectors have answered wonderfully well. But would they produce like results in other hands—I mean, of course, would the *average* photographer readily acquire the necessary skill in the manipulation of his three reflectors, top, side, and front light? I rather think not; but if one large reflector were used, successful gas-light portraiture would be easily available for all. As Mr. Laws mentioned recently in your pages, what is required is a properly-constructed reflector that will utilize every ray of light, and be easily adjustable.

If some of your contributors would now give their attention to the subject, we might have the desired reflector in our studios in time for the winter harvest.—Yours truly,

WILLIAM THWAITES.

MASTERS AND MEN.

SIR,—Allow me a brief space in retaliation of last week's remarks, made by a would-be operator who styles himself by that name; in name only, as I have too often found to my great sorrow and disappointment, during the time I have been in business. Unfortunately, too, their name is legion, a disgrace to the profession. Such men as those who formerly obtained employment on the stage or music halls, but who know no more of the business than a school boy. These are the men who ruin our trade, who drive customers from our door by their vilifying pretensions to photography. I

will also refer to their drunken habits. The bare idea of a man engaging himself to fill a respectable situation as first-class operator and retoucher, coming into the shop in a state of drunkenness, trying to extort money from the mistress of the establishment before even entering on the duties allotted to him. I could tire my readers with the many cases of this sort which I have been brought into contact with since I commenced business, and those who have been similarly tried can sympathise with me.

Having gained a name and reputation in the old city to which I belong, I do not feel disposed to sacrifice it for the sake of those swindlers—for they deserve no better name—and only now can I say, after many years of trouble and annoyance, have I found an efficient operator, one who is master of the art, whose services I can appreciate.—Yours, &c.,
EXONIAN.

To Correspondents.

PHOTO.—The general proportions and plan of your projected studio are very good. The best side light is one facing north, illuminating the sitter with north light. No. 1 will be the most useful lens.

BEGINNER.—There is probably no operation in photography more easy and simple than the production of ferrotypes, and we should recommend any operator to master the details. They are chiefly required in cheap businesses, and are probably rarely in demand in first-class studios. Most of the good negative collodions now in use may be employed in ferrotype work.

GLAZING PRINTS.—A correspondent, whose letter is mislaid, asks what is applied to prints, previous to rolling, to secure the very high gloss he sometimes sees. We presume that he refers to the surface produced by what is called enamelling. The effect of wax and encaustic pastes is to give a polish to the surface of the finished print, and also to preserve it from the action of a moist atmosphere; but they do not produce that glass-like surface which is obtained by the enamelling process. It would require too much space to describe in this column the process of enamelling, but we may briefly indicate its nature. A piece of plate glass is well cleaned, and then polished with bees' wax. It is then coated with a thick, tough, uniodized collodion. When dry, this is coated with solution of gelatine, which is allowed to set—or, as some prefer it, to set, and thoroughly dry. The prints, having been properly washed, are placed, whilst wet, face down upon the gelatine, and all air-bubbles and water carefully squeezed out. The prints are left to dry, when they will curl off the glass, or easily lift off, and bring with them the gelatine and collodion films, and present that glassy surface which many admire. It is, we think, an improvement to small pictures, but its application to larger prints is of doubtful value. It is probable that it conduces to permanency.

G. F. L. M.—Various methods may be employed in developing paper prints. Some immerse them in a dish of the developing solution. Some float the print, as the paper was originally floated, on the silver solution in sensitizing. A good plan consists in turning up the edges of the exposed paper, and binding them at the corner by means of an American clip, so as to form a dish. The developer is then poured into this dish with a rapid sweep, so as to cover the surface as quickly as possible, and is then rapidly distributed over the print by means of a Blanchard brush, consisting of a piece of swan's-down cotton tied over the end of a stout strip of glass. Some operators use such a brush for applying the silver solution in sensitizing, and use the same brush in developing to such parts of the print as may require to be a little darker, the silver it retains mingling with the developer to give greater intensity. As a rule, a saturated solution of gallic acid is used for development. If a plain silver solution were employed in sensitizing the paper, a little acetic acid is added to the developer; but if acetic acid have been added to the silver bath, none is required with the developer. A saturated solution of gallic acid is made by dissolving it in hot water, at the rate of about five grams to each ounce of water. The discolourment of which you complain is often caused by plunging the developed print into the hypo fixing bath without previously washing well.

FACTOTUM.—As a rule, an operator is not called upon to print; but if he is wise he will willingly do anything in any department of the business that he is able, from cleaning a plate to retouching a negative, from printing a vignette to applying encaustic paste to the finished print.

Several correspondents in our next.

The Photographic News, August 1, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

FORGERIES AND PHOTOGRAPHY—ADVERTISERS AND PERSISTENCE OF VISION—YELLOWNESS IN ALBUMENIZED PAPER.

Forgeries and Photography.—The recent forgeries on the Bank of England bring us back to the subject of detecting such doings by means of the camera. The falsifications in this case were made upon cheques issued by the Bank of England, which, as our readers are aware, bear no coloured printing at all. They are simply black and white. But they are very delicately engraved, and this is held by many to be a better safeguard than the employment of tints of various colours. These, of course, were introduced for the purpose of preventing reproductions being made by the aid of the camera; but since the discovery was made, two years ago, that the blue bank notes of the Bank of France offer little difficulty to the ingenious photographer, it is obvious that colours are not the safeguard that is supposed. Indeed, in the opinion of many, the printing of a tint upon a cheque or valuable paper is a source of weakness, rather than of strength. When a document in black and white has to be imitated, it is necessary that the imitation should be a perfect one, otherwise the fraud is at once detected; but if colours are introduced, these may be made to cover the imperfections of the forgery in a measure, and thus serve to cloak clumsy execution. In the present case, however, it is no fraudulent manufacture of a cheque that is in question, but rather the removal of characters in ink, and substituting others. A portmanteau has fallen into the hands of the police, containing, we are told, the necessary chemicals and implements for making these changes. The chemicals referred to were, no doubt, oxalic acid (or salts of sorrel, as it is generally called), or, perhaps, citric acid, but very great care would be necessary in the employment of these, if detection is not to ensue; for before paying a heavy sum in favour of a person who does not usually draw large amounts, there is, we presume, some amount of caution exercised by a banker's clerk. The removal of an ink stain from the surface of paper must be very cleverly managed if it is not to leave a stain behind, and we doubt whether any means short of immersing the document in liquid would be successful. In this case it would be necessary for the forger to protect the signature, and, possibly, also the date, but this could be done, possibly, by the use of a pale varnish. But do it in any way he chose, we do not see how he could possibly evade detection if such a document were passed for examination into the photographer's department, like that established in Paris, in the Bank of France. A collodion picture, quickly taken, of a cheque so treated would at once show inequalities over the surface, and if the slightest stain of the yellow iron solution remained, this would be rendered particularly apparent. So that photography, instead of being an enemy to bankers, as these naturally expected, turns out to be capable of furnishing them with a means of detection much more delicate than the eye of an experienced cashier. If varnish, or any protective coating, had been but partly applied to a cheque, evidence of it would be at once furnished by the camera, while, as we know, the slightest crasure becomes at once apparent. Moreover, if a figure or character has been erased to the eye, it by no means follows that the camera cannot see it. Any photographer who has copied a portrait which has been at one time or other enclosed in a letter knows this. The face of the print may be white and spotless, and yet, when a copy is made in the camera, there are to be seen crossing the face of the picture a startling imprint from the writing which was for some time in contact. Several examples of this have come under our notice, and the defects in most cases

are so glaring that they quite spoil the reproduced photograph.

Advertisers and Persistence of Vision.—The study of persistence of vision is decidedly interesting in itself, and by the photographer it has frequently served as a pastime. Herr Ball's recent investigations upon the visual purple of the eye, the results of which prove that not only is the human retina impressed with an object in a photographic sense (if the object is seen long enough), but that there is behind the purple film another tissue, which acts as a resensitizer, have interested photographers a good deal, as it is only natural they should do. In fact, photographers must obviously feel an interest in all which pertains to optics and to the impression of colours, either upon organic or inorganic films. Perhaps that is the reason why an extensive advertiser has bethought himself to blend optical science with publicity. The idea is a happy one, both in design and execution, for as the object of all advertisers is to impress themselves on the public, if this can be done in carrying out a scientific experiment, the impression is likely to last all the longer. Mr. Buggins Brown has therefore hit upon this clever expedient. He prints a block of shining red, and below it is an empty space of white. In the middle of the red square appears in white the name Buggins Brown, and if you look at this red square with the white letters in a good light for twenty seconds (so runs the advertisement), you will afterwards see in the blank space below a square of bluish-green with the name Buggins Brown in white. Green being, of course, the complementary colour to red, the eye would naturally see the former after it had been fixed firmly for some time on the latter pigment; but whether in the advertisement in question matters are so well arranged as to permit the illusion, we do not know, since we had no desire to gaze upon the name of Buggins Brown in its inflamed setting for a period of twenty seconds. Notwithstanding the lucid explanation, we rather doubt it. But probably it is of little moment, after all, to Mr. Buggins Brown whether you have seen his name thus transposed or not, so long as he has prevailed upon you to stare at the red square for a full third of a minute. Nay, the ingenious inventor himself rather betrays a lack of belief in the scientific phenomenon, for beside the blank space, if he should see nothing else, he will read these words: "There are some few persons to whom exceptionally these phenomena will not be apparent, they are assured that no foolish trick has been attempted." The affair reminds one strangely of Mr. Toole's peepshow, which that excellent comedian shows upon occasions; to the spectator who looks bewildered into the empty box in the vain endeavour to obtain a glance of "the lowest dungeon of the castle keep," it is coolly explained, "You will observe the dungeon is a perfect cell."

Yellowness in Albumenized Paper.—It would be interesting to know whether a pigment, or tint, could not be added to albumenized papers for the purpose of correcting the yellowness with which time, apart from any influence of silver, impresses it. A purely-white albumenized paper, if exposed to direct sunlight for a few months (before being sensitized), not unfrequently assumes a yellowish, or, at any rate, a dingy tint. This may be due to the sulphur contained in the albumen becoming attacked by vapours of one kind or another, or by the bleaching compound that has been used being acted upon. Whatever the cause, many albumenized papers certainly do become *dejaichi*, or robbed of their freshness, by exposure to air and light, and it would be well worth the attention of manufacturers to see if this could not be counteracted in some way. In the manufacture of pigment tissues, measures have to be taken to render the slight yellowish-brown tint of the insoluble chromate invisible, and in the same way, we think, a pigment might be added in minute quantity to neutralize such change as the albumenized paper undergoes in its normal condition.

SOME EXPERIMENTS WITH THE RARER SALTS OF SILVER.

BY DR. GUIDO WOLFRAM.*

In all the works to which I have access, I have been able to find very little information as to the photographic properties of silver fluoride, while the chlorate and perchlorate of silver do not appear as yet to have been used at all for photographic purposes. Hallem, in his treatise on the "Art of Photography" (page 74), states that silver fluoride, like silver nitrate, undergoes but little alteration under exposure to light; but that, in combination with silver bromide, it appreciably raises the sensitiveness of the latter, especially when sodium fluoride is used in preparing it. He soaked some paper in a solution of potassium bromide and sodium fluoride, dried it, and silvered it, and then rinsed it well with water. By exposure in the camera, and development with iron sulphate, he obtained pictures.

In the same way as Hallem, G. Wharton Simpson (*Photographische Mittheilungen* VI., page 313), Sir J. Herschel, and Robert, have attempted to take photographs with silver fluoride in combination with silver bromide. Blanquard Evrard found that albumen plates containing the iodide and fluoride of silver were so excessively sensitive that he was able to take instantaneous photographs with them; he also observed that under similar circumstances silver iodide alone was sixty times less sensitive to light. Wharton Simpson soaked a piece of paper in a 50-grain solution of silver fluoride (how he prepared it is not stated), and exposed it in conjunction with two other papers coated with chloride of silver collodion to direct sunlight; the silver fluoride paper exhibited in five minutes scarcely as much change of colour as the others in one minute. Of papers prepared in the same way, exposed for a minute to diffused daylight, and subsequently immersed in a saturated solution of pyrogallie acid, the silver chloride papers turned a light-brown colour, but the silver fluoride papers showed a splendid chestnut brown. For this reason Simpson recommends silver fluoride for taking enlargements.

In H. Vogel's "Manual of Photography," page 128, it is stated that silver fluoride undergoes a change even in the yellow. The January number of the *Photographische Correspondenz* for 1878 contains an article by Husnik entitled "Collotype in Natural Colours," in which there are some remarks on the sensitiveness of silver fluoride. Husnik states that he has found the iodide, bromide, chloride, and fluoride of silver to be sensitive to all rays after a short pre-exposure. The salts of fluorine must be used in such a way that only sodium fluoride comes into contact with the iodide, bromide, and chloride of the same metal, inasmuch as the salts of the other metals give insoluble compounds with it. Husnik's process appears to consist in dissolving these four salts (either together or separately) in collodion, and then by acting on it with a solution of nitrate of silver to produce the corresponding haloid salts of silver. Independently, however, of the difficulty of introducing silver fluoride into collodion on account of its comparative insolubility in alcohol, it is quite impossible to obtain the salt by the method indicated. Soluble salts of fluorine give no precipitate with silver nitrate, for fluoride of silver dissolves readily; there is also no conversion of the two salts into sodium nitrate and silver fluoride, for when brought together they remain side by side unchanged.

Silver fluoride is best prepared by dissolving silver oxide or carbonate in hydrofluoric acid; by evaporating the liquid we get the unstable and, as Berzelius showed (*Poggendorf's Annalen*, I. 35), the highly deliquescent salt. It is as difficult to obtain the chlorate and perchlorate of silver, as the silver fluoride, if the plan be adopted of acting on silver nitrate by the respective alkaline salts.

* *Photographische Mittheilungen.*

These two salts are also both highly soluble, and are best prepared by dissolving silver oxide or silver carbonate in chloric and perchloric acid respectively, or by the double decomposition of the barium salts acting on silver sulphate. If pieces of Rive paper in an unfinished condition be soaked in silver fluoride, and in chlorate, perchlorate, or nitrate of silver, the first will turn a light brown colour still floating on the fluoride solution, while those soaked in the other salts remain white after drying. The silver fluoride paper changes colour when exposed to light, quicker than the other three, and those three take the same time to darken. A reduction of the chlorate and of the perchlorate of silver to the chloride does not appear to take place in the substance of the paper itself, or the colouring would become more intense. Under red and yellow glass the silver fluoride paper does not change colour any more than the other papers. Paper soaked in solution of silver fluoride or nitrate, dried, and then washed with pyrogallie acid, turns a deep chestnut brown, even without exposure to light. The production of pictures in the manner proposed by Wharton Simpson is therefore not possible.

Attempts to replace silver nitrate by one of these more soluble salts for the sake of shortening the time of exposure were not successful. Silver chloride, chlorate, and perchlorate employed as sensitizers for silver iodo-bromide neither effected a decrease in the time of exposure, nor showed any other advantage over silver nitrate. With the first two salts very good negatives were produced by the help of an acid iron developer; with the last-named—silver perchlorate—notwithstanding strong acidulation with nitric acid, the reduction of the salt was so rapid that the plates were covered with a dense veil.

As I have above stated, when sodium fluoride and silver nitrate are brought together, a double decomposition does not take place. Although in the majority of cases it is impossible for the chemist to prove whether a double decomposition has taken place or not when two soluble salts are mixed together without producing a precipitate, in the present instance the greater sensitiveness of silver fluoride shows at once that the two salts exist side by side in an unaltered condition. If paper be soaked in a mixture of sodium fluoride and silver nitrate, or be first treated with sodium fluoride, and, after drying, with silver nitrate, the result is a paper of the same degree of sensitiveness as one soaked in silver nitrate alone. For this reason Hallem found the sensitiveness of his supposed silver fluoride to be as great as that of silver nitrate.

A mixture of potassium chlorate and silver nitrate could not be distinguished from silver chloride by the test of the sensitiveness of the papers treated with those salts. But I have succeeded in finding for this case also a reaction by means of which the difference between the two solutions can very clearly be shown, and by which it can be proved that a double decomposition does not take place. From a mixture of potassium chlorate and silver nitrate, silver nitrate is thrown down in the form of a reddish yellow precipitate by means of potassium nitrite; whereas a solution of silver chlorate is reduced by the same reagent to silver chloride. In the first case the precipitate is soluble in nitric acid, nitrous acid being given off; while in the second case the precipitate is insoluble in nitric acid.

The results of the experiments above-described go to demonstrate:—(1.) That a mixture of a solution of sodium fluoride, or of potassium chlorate or per-chlorate, with one of silver nitrate, will not produce silver fluoride nor silver chlorate or per-chlorate. 2. That silver fluoride in the presence of organic reducing substances is more sensitive to light than silver chlorate, per-chlorate, or nitrate. 3. That silver fluoride, chlorate, or per-chlorate, when employed as sensitizers of silver iodo-bromide, neither decrease the length of exposure, nor offer any other advantage over silver nitrate. 4. That silver fluoride has not been observed to possess sensitiveness to the yellow rays.

PHOTOGRAPHY AS APPLIED TO THE REPRODUCTION OF PLANS AND DRAWINGS.

BY DAVID TOWNSEND, B.S.*

2. *Sensitizing.*—We now come to the second operation, namely, sensitizing, or applying a substance which will be affected by the light. In this case we use nitrate of silver, the theory being that when the salt in the paper comes in contact with a solution containing the nitrate, chloride of silver is precipitated, which forms an exceedingly sensitive surface, in the presence of an excess of nitrate of silver and organic matter.

The silver bath consists of:—

Cryst. silver nitrate	1 part.
Citric acid	$\frac{1}{2}$ "
Alcohol,	1 "
Distilled water	10 parts

The pure crystallized nitrate of silver is dissolved in one portion of the water, the citric acid in another, and the solutions added, together with the alcohol. Paper sensitized with this bath will keep unaltered for months, whereas, if only nitrate of silver and water had been used, it would turn yellow in a short time. Enough of the bath should be made up to float the paper without touching the bottom of the pan. The vessel in which the sensitizing is performed consists of a tin pan, thickly painted with asphalt, which, when dry, is coated by means of a brush with melted wax. This, when cold, forms a good lining which is not in the least affected by the silver, and which does not affect or contaminate it. I have used such a pan for months without any perceptible change in either the pan or bath. This forms a cheap and desirable substitute for porcelain, which would be difficult to get sufficiently large. The manipulation of the paper is the same as described under the head of salting, being shortly as follows:—The paper is taken at two opposite corners and bent evenly without making any creases or breaks. It is then held over the bath and lowered gently until it touches the liquid. One corner is then lowered until half the paper lies on the bath, then the other is treated likewise. The paper should always be rolled with the salted side out, otherwise the edges will dip into the bath on floating it, and cause spots on the back. When the paper is very large it is necessary to have an assistant to prepare it properly. If any bubbles appear under the paper, they must be carefully removed with a glass rod; but when the sheets are large, it will be more convenient to touch the spots with a clean brush moistened with the solution on taking the paper off the bath. The paper is allowed to float for one minute in winter, and forty to forty-five seconds in summer. The temperature of the bath is also important, because if it be ice-cold, sensitizing will proceed very slowly; therefore it is best to warm the liquid slightly in very cold weather. The paper is just the opposite, as it keeps best when cold. Sensitizing should be performed in a dark room, photographically speaking; that is, in a room lighted only by such colors as have no actinic action on sensitive substances, such as red, orange, or yellow. My own laboratory is arranged with heavy yellow shades, put on rollers which slide in grooves; thus I can have actinic or non-actinic light at pleasure by simply raising or lowering the shades. It would be well to have such an arrangement, as all the operations to the final washing require to be performed in non-actinic light. Care should be taken not to let the silver solution wet the back of the paper, and to avoid touching it with unclean fingers, as black spots will appear when the sheet is exposed, and mar the beauty of the drawing. When the paper is sufficiently sensitized, it is drawn carefully from the bath, and suspended from a line, by compression pins, to dry. A piece of blotting-paper should be placed under it to catch the silver solution which drops off, and which may be regained. The silver bath should be occasionally tested for strength, and, if weak, the proper

amount of new nitrate added. It may also become cloudy, due to organic matter, but this may be removed by adding a few drops of potassium permanganate in water (1 to 100), or until a faint pink colour is produced, then putting it in the sunlight for several hours. Silver stains on the hands may be removed by rubbing them with cyanide of potassium and water; but as this salt is a deadly poison it should be used with great care.

3. *Exposing.*—Next is the exposing of the prepared sensitive paper to the action of light, under a drawing, in order to produce a copy. The theory of the operation has been explained; it is carried out in what is known as the printing-frame (fig. 1). This consists of a wooden box having four shallow sides, two to four inches in height, the front being a piece of plate glass, fitting in the frame, and the back (C) consisting of two pieces provided with hinges

so that either side may be opened without disturbing the other. The back is pressed tightly against the glass by means of a couple of springs (A and B) fastened on two cross-pieces of wood held by catches and hinges to the frame. To the back is glued a soft piece of Canton flannel, which presses against the glass. These frames may be procured ready made from three by four inches up to twenty by twenty-four inches, and other sizes may be had to order. The frame is carried into the dark room, the back removed, and the drawing, if on tracing-paper, is put in with its right side against the glass; the sheet of prepared paper is then placed with its sensitive side against the back of the drawing; two or three thicknesses of Canton flannel are next laid in, and then, after making all as smooth as possible, the back is replaced, and the springs shut. If, on turning it over, any wrinkles appear, that side of the frame is re-opened, and a piece of paper put against the spot, when all will come smooth on again closing the frame. The frame is now carried into the light, and left until the paper turns brown, which it will do in a short time. It is then carried back and opened, or, if not in sunlight, it may be quickly examined without taking it to the dark room. If all the lines are still white, it must be closed, and again exposed to light; but if the white lines are slightly brown, the exposure is sufficient. In every case the print should be over-exposed, as it fades considerably in the subsequent operations. No special directions need be given in regard to time, as it varies considerably, and is, besides, easily controlled. The picture produced will be a positive, or like the original, except it will have white lines on a dark ground. In order to produce dark lines on a white ground, two prints are required to be made, one reversed, which is finished and then used as a negative to produce the desired positive. Drawings made on tracing cloth may be printed either as positive or negative at will; but where the original is on regular drawing paper, a negative only can be produced, owing to the thickness of the paper. Originals made on paper that is soiled, or yellow from age, cannot be copied, because the colour makes them non-actinic. It would be well to remember that the more opaque the lines of the

* Continued from page 341.

original, the better will be the copy, therefore we make use of the non-actinic properties of certain colours, and mix brown, vermilion, or yellow with the Indian ink used in making the drawing. It is a good plan in large establishments, where a great many copies of one drawing are required, to pencil the original on paper, and finish only the tracing, which may be kept as a negative to reproduce any number of copies. My own experience has been that tracing cloth is much better than paper, as it is less liable to tear or wrinkle, and gives more accurate results.

4. *Washing*.—After obtaining a sufficient exposure, as directed above, the frame is brought into the dark room, and the picture removed; it is then put in a pan of sufficient size, arranged so that water may run in at one side and out at the other, and left until the water becomes clear. If this cannot be conveniently accomplished, it is placed in a pan and the water changed four times. Now, as all the parts protected from the light still contain nitrate of silver, this will be dissolved in the water, and it becomes a matter of economy to recover it. When the print is small, the water may be preserved in a keg, and the silver extracted at leisure; but where running water is used, other means must be resorted to. The easiest way is to place two old felt hats, each containing a handful of common salt, under the exit pipe, when the silver, in passing through the salt, will be precipitated as chloride, and caught in the fibres of the felt. In the course of time the hats will become saturated, and may then be dried, burned, and the silver extracted. The next two operations, viz. (5) toning and (6) washing, are seldom performed for copying drawings, but the print is immediately fixed after being washed. For very fine line engravings, or for copying photographs, they are important, and so I will describe them.

(To be continued.)

PHOTOGRAPHY IN COURT.

The following cases, in which photography appears in Court, may interest our readers.

THE PHOTOGRAPHER AND HIS TRAVELLER.

Furrier v. Hudson.

This was a claim for £17 10s. for wages and expenses. Plaintiff is a traveller, of Walworth, and defendant is a watch-maker, of Ely Place, Holborn, and also trades under the title of "The Cornhill Photographic Company."

Mr. Batts appeared for the plaintiff.

Previous to the commencement of the latter business defendant advertised for travellers. Plaintiff communicated with the defendant, and the result of that communication was that plaintiff was engaged as traveller, his principal duty being to find agents who would undertake the formation of clubs. For performing this work he was to receive a salary of £10 per month, payable weekly, with an extra allowance of 18s. per week for expenses. Plaintiff's wages and expenses were paid in accordance with this agreement up till the 10th May. On that date he called as usual, and found the defendant out, his salary being left, minus the "expenses." The same course was adopted on two or three subsequent occasions, and in answer to plaintiff's remonstrances, the defendant wrote to him, stating that as his efforts in the business had not been attended with the least result, his services would be no longer required. Plaintiff responded to that communication, expressing his surprise, as he had conscientiously endeavoured to do all he could for the defendant's business.

In answer to his Honour defendant said he had refused to pay this amount because plaintiff had obtained the situation by false representation. He (defendant) had been given to understand that the plaintiff had failed in business, and had paid fifteen shillings in the pound.

His Honour: Do you call that a recommendation?

The Defendant: Yes.

His Honour: Well, I suppose it is a good recommendation in these days.

The Defendant: We are not inclined to judge of a man harshly who—

His Honour: Who does not pay his debts?

The Defendant: No; a man who has struggled hard to pay a good dividend. Defendant further said that the plaintiff had attended races instead of trying to obtain agents.

His Honour said attending races was not in opposition to his agreement. He should have thought that racecourses were very good "touting-places."

The defendant said plaintiff went to the Alexandra Palace races on at least two occasions.

His Honour: And what other places? Did he go to the Crystal Palace. (Laughter).

Plaintiff denied that statement. He went to the boat race, and received the defendant's assent to go.

His Honour said the plaintiff had not guaranteed to the defendant that he would succeed. All he had undertaken was to "tout" for them. He had done his best, though he had failed, and therefore judgment must be in the plaintiff's favour, with costs.

Judgment accordingly.

THE PECKHAM RYE PHOTOGRAPHER.

William Hambly, 34, photographer, was indicted for an infringement of the bye-laws for the regulations of Peckham Rye, by keeping a photographic apparatus on the common on Sundays, contrary to the regulations of the Camberwell Vestry. It appeared that the defendant held a licence from the Vestry to keep this photographic apparatus on the Rye for six days a week, but he insisted upon occupying the common on Sundays also. To this the Vestry objected; but as the bye-laws provided no penalty in case of infringement, they were compelled to proceed against the defendant by an indictment in common law.

Mr. Lilley, for the defendant, raised a question as to the right of the Vestry to make bye-laws, but his objection was overruled by the chairman, who declined to grant a case for a superior court.

The jury, by direction of the Court, returned a verdict of guilty, and the chairman said, as the object of the Vestry was simply to restrain the defendant from infringing their bye-laws, the Court would not inflict any punishment, but simply order him to enter into recognizances to come up for judgment when called upon. Of course, if he again offended, a penalty would be inflicted.

The *South London Press* has the following remarks on the above case:—

An important case has just been heard at the Surrey Sessions. For some time past the Camberwell authorities have been set at defiance by certain members of the vagabond class who persisted in taking possession of Peckham Rye, to the detriment of the public, which resorts there for recreation and amusement. The inspector appointed by the Vestry was quite unable to restrain the rough element within moderate limits, and so serious did the nuisance become, that an impression got abroad that the Vestry was altogether powerless to exercise any authority over the management of the Rye. This impression was brought about partly by a commendable leniency on the part of the Vestry, but more directly through the influence of certain members of that body, who were imprudent enough to express a doubt as to the legal power of the Vestry to enforce the bye-laws it had made. Under these circumstances, no option was left to the authorities but to assert its power; and this it has now done in the most complete and successful manner. It is perhaps to be regretted that the person proceeded against was not the most notorious nor the most objectionable offender. For some time past, the person prosecuted has carried on, with more or less success, the business of photography on Peckham Rye. He held a licence from the Vestry to carry on his trade six days in the week; and, in an evil hour for himself, he was persuaded that the licence was nothing worth, and that he could continue his business on the seventh day without let or hindrance. With this conviction strong in his mind, there is some excuse for his conduct, for Sunday, doubtless, offers the largest scope for business, when the lads and lassies in their "Sunday best" fall an easy prey to his seductive appeals. The finding of the jury on Tuesday last, which brought him in guilty of a breach of the bye-laws of the Vestry, will doubtless act as a salutary deterrent to other offenders; but should the judgment fail to influence the conduct of roughs who at present set the law at defiance, we trust the authorities will act promptly in the matter. The recent decision has clearly established the Vestry's title and the legality of their bye-laws, and these are points gained in the interest of all who desire our open spaces utilized for the benefit and recreation of the people.

PRINTING PERPLEXITIES.

BY H. C. BRIDLE.*

HAVING been applied to frequently during the last two months to give some method for preventing the albumen softening, and leaving the paper during the fixing or washing, I thought a few words on the subject might be useful to some of your numerous readers. To make the matter perfectly intelligible, I will describe the whole process of silvering, toning, &c.

First, as to the treatment of paper. Keep the paper

* *The Philadelphia Photographer.*

from twelve to twenty-four hours before silvering in a damp, cool place. This applies to every brand of albumen paper. It gives greater ease in silvering. The paper will take the silver better, and will also lessen the tendency to blisters to which the "Brilliant" papers are especially liable. Prepare a plain silver solution—

Nitrate silver	35 grains
Pure water	1 ounce

Test with litmus paper. It should be just alkaline. If it is not, make it so by adding a few drops of dilute ammonia, till the pink litmus-paper just, and only just, turns blue. Float the paper sixty seconds; draw over a glass rod. Carefully examine the first sheet you silver each day, as it begins to get surface dry. If it looks as though the surface was greasy, reduce the strength of your silver solution. Dry as quickly as possible. Fume with ammonia until the paper prints a rich purple. Ten minutes will probably be sufficient. Be sure that, when the paper is once dry after silvering, it does not get damp again until it goes into the washing. In damp weather, see that the fuming-box is dry. If damp, light a lamp, and leave it burning in the box for a quarter or half-an-hour before putting in the paper. The paper should show a little, but very little, bronzing in the deep shadows when fully printed under a good negative. When the printing is finished for the day, proceed to tone. Place the prints one by one in water made slightly acid, and leave them till they begin to lose the blue colour. Pass them through at least three changes of water, and then into the toning-dish. Use any good formula for toning. I prefer the sal soda bath, made every day about half-an-hour before you want to use it. The prints should tone in about six minutes, certainly not longer than twelve to fifteen. Tone till the lights look rather blue, and then place the prints in a dish of water till all are toned. Now proceed to fix. See that the hypo is not acid. It should be neutral, or even slightly alkaline. The hypo should be made up fresh every day, especially during the summer.

Drain the prints well from the hypo, and place in strong solution of salt for five minutes, moving them about all the time, and then putting them in running water for three hours. It is better to make the hypo and salt solution two or three hours before using it, as both hypo and salt make the water several degrees colder. The neglect of this is one common cause of blisters, &c. Any of the American brands of paper will work and give good results if this method is adhered to. The German "Brilliant," such as the "Dresden Brilliant," "S. and M. Brilliant," or "Cross-sword Brilliant," will need a stronger silver solution, especially if the solution is new, as a new bath needs to be at least five grains per ounce stronger than an old bath to give good results. If the German "Brilliant" paper is silvered on a new bath of not more than thirty-five grains strength, it is quite probable the albumen will soften and rub off. If this does occur, strengthen the bath by adding more silver. Test the strength of the solution every day. Do not use the hydrometer, but use "Pile's Test-tube." This is the only reliable means of testing the strength of silver solution. The hydrometer registers everything that is held in solution, while the "Pile's Test" only takes account of the quantity of silver in solution.

Doubtless to the larger portion of the readers of your valuable journal there will be nothing of service in this letter. The desire to benefit those who have had but little experience in this very important branch of our business must be my excuse for occupying so much of your space.

MEASURING DAYLIGHT.

The Times, speaking of the importance of registering the variations of daylight, says:—"It is greatly to be desired

that a good and simple method may be found of recording and measuring with some accuracy the variations of daylight throughout the day. This would render the weather record more complete, and it has an important special bearing on plant physiology. An attempt of the kind has lately been made by a German, Herr Kreisler, who has had made for him, by Liebertz, in Bonn, an apparatus with the following arrangement: It consists of a drum fixed with its axis in the plane of the meridian, and adjustable so as to be at right angles to the sun's rays. This drum has its border divided into twenty-four hours, twelve noon, twelve midnight being in meridian plane. A strip of paper, sensitised with solution of bichromate of potassium, and having divisions which correspond to those on the drum, is placed round this. A second drum closely surrounds the first, and is turned by clockwork (from which it can be detached) once in twenty-four hours, in the direction of the sun's apparent course. This second drum has a slit for admitting light to the paper; its width is such that any point on the paper is exposed twenty seconds as the slit passes over. The whole apparatus is placed in the open air under a glass bell-jar. Its arrangements give little trouble: the paper strip has merely to be placed in its proper position at night or under artificial shade (to avoid colouration), and the outer drum slid over and so attached to the rotating axis that the 'isolation slit' is opposite the hour then present. The slit then begins to move around the inner drum correspondingly to the sun's course. The impressed slip, when removed in the evening, may be 'fixed' by shortly dipping in water and drying between blotting-paper, or it may not, being quickly read; it shows a mostly continuous succession of bands of various shades of black, or rather brown. For comparison, Herr Kreisler made a scale of ten degrees of darkening, exposing strips of the paper a given time under different angles of incidence of light. Bands of the experimental strip that appear homogeneous are now measured with reference to breadth (minutes and seconds) and intensity (by comparison with the scale), and the sum of the products of these quantities is taken as a measure of the action of light rays falling on the instrument in a given time. The results are considered highly satisfactory."

RECOVERING SILVER FROM PAPER.

Mr E. STEFFEN, writing in the *Photographisches Archiv*, says:—

"The following process does not require much trouble and outlay. The papers are, as usual, burnt up, which is best done in a common stove which has been cleaned, and after the draft has been half turned to prevent the flying off of the ashes. When thoroughly burned, the cold ashes are gathered up in a glass vessel, and diluted muriatic acid poured over, which must be done, however, only by short degrees, as the mixture will be agitated very much by the development of the carbonic acid. After the development of the gas has ceased, and the mixture has been well stirred and acidulated, it is left alone over night, which causes the foreign substances to be mostly dissolved, which can also be reached quicker through warming. After filtering and washing with rain-water, the residue is dissolved at once in diluted nitric acid, which is done very fast. The nitric acid must also be poured in only gradually, to prevent foaming over. The residue consists of some sand and carbon, which is filtered off.

"Let evaporate, melt, redissolve, and crystallize, and a very pure nitrate of silver (oxide) is obtained for negative baths. The loss of silver is in this process much less than in remelting the ashes in the crucible, which also is very tedious.

"In an experiment which I made, I obtained from 9 kilogrammes remnants of paper, 308 grammes ashes, which weighed, after treatment, 228 grammes. Dissolved in nitric acid, the ashes yielded recrystallized white nitrate of silver oxide, equal to a percentage of 67.5 per cent. of pure silver."

SUNDAY PHOTOGRAPHY.

A CASE which has excited some interest in South London has recently been decided at the Surrey sessions. A photographer, it seems, had selected the common at Peckham Rye as a suitable "pitch" for securing a clientele among the wanderers in the neighbourhood. How far the exercise of "common rights" warrants the establishment of a photographic studio on the ground we cannot tell; but it appears that the photographer had made his position safe so far, inasmuch as he held a licence from the proper authorities—the Camberwell Vestry. This licence only extended, however, to the ordinary working days recognized by law in this country; but, ill-advised, or over-hold, or possibly enterprisingly experimental, and desirous to test the question, in defiance of the warning of the Vestry he maintained his position and practised his profession on the Sunday as well. This act on the part of the photographer formed one of a series of annoyances in the shape of Sunday occupation of the common which the Vestry felt bound to put down, the more so, as a disposition to ignore the right and power of the Vestry had been manifested; and an indictment at common law issued in the conviction of the offender, and the infliction of a mild sentence, instead of a vindictive penalty, in order to restrain the defendant.

Leaving the question of common rights and the claims of squatters to be settled by law, as we presume they always must be, we take occasion for a few brief words on the professional practice of photography on Sundays, a subject which has frequently been brought under our attention by correspondents, but which we have generally felt indisposed to treat in these pages. Any extended discussion of the matter in a theological sense would be obviously undesirable in a scientific journal. The nature and extent of the authority for the observance of the Christian Sunday in the same manner as laid down in the Mosaic law for the sabbath would be, undoubtedly, a very interesting question in suitable pages. That the observance of the first day of the week as a day of rest and special religious duty is not based upon biblical authority seems to be tolerably clear; but that it is an outcome of that Christian civilization which has done so much for the world, and is so precious to mankind, is scarcely less clear. Some of our American friends have been discussing the matter somewhat earnestly in relation to its religious aspects. In the *St. Louis Practical Photographer* it has had considerable attention. We quote some remarks written in a wise and philosophical spirit by one of the contributors, who enters as fully into the theological question, probably, as it is desirable to go. He says;

"The aborigines of this country have no Sabbath. I am not aware of any heathen people who have one. The Sabbath was a Jewish institution; the present Sunday is indisputably a Christian one, intended to supersede the Jewish precedent, upon which it is founded. If I understand the matter correctly, the days of the week were not named in what are termed 'Bible times,' by which I understand the era from Moses to Christ—the seventh day alone being named. The names in common use are partly Roman and partly Saxon. The Romans gave us Saturn's day, Sun's day, and Moon's day, the first, second, and seventh days of their week having been devoted to the worship of the Sun, the Moon, and the Roman deity, Saturn. Our Saxon ancestors gave us Thew's day, Wodin's day, and Thor's day, representing deities of the masculine gender, and Freiga's day, Freiga being the Saxon goddess of love, equivalent to the Roman Venus. We thus have four Saxon heathen names, Tuesday, Wednesday, Thursday, and Friday, and three Roman heathen names, Sunday, Monday, and Saturday. That Mrs. Brown is right in her position that Sunday does not represent the Jewish Sabbath is undeniable. That Elrod is right in claiming a cessation from labour on Sunday, because the law recognizes that day as a day of rest, and has by legislation prohibited unnecessary labour on that day, is likewise indisputable. That experience proves the necessity of a season of rest, as a sanitary measure, I think no one will dispute; and I think those who know the history of the attempt to banish the Sabbath from France will admit that one day in seven is as near the necessary amount of rest as human wisdom has been able to adopt. Now let me propound a question to those who are very touchy in regard to their rights in the matter of religious freedom: Where did religious freedom get its birth? Was it in the East, where, from the Brahmin to the Pariah, every sect despises and ostracizes every other? Was it from the West, where the Aztec priest immolated on the altar, as a sacrifice to his god, every captive he could lay his hands on? Was it from the South, where the Australian made a feast and ate those who thought differently from the tenets taught by his ancestors? In Asia, to-day, it is as much as a man's life is worth to hint at religious freedom except under the guns of the British soldiery. Where has civilization advanced most rapidly—under the rule of those who respect the Sabbath and defend those who desire to do so, or under the rule of those who despise and reject it? Where is a man's life held cheapest—under Christian or pagan rulers? No need to pause for a reply. Outside of the limits of Bible law woman is a slave, bought and sold, like a horse or a dog; her very life at the mercy of the savage who owns her. In the territory subject to Buddhism and Brahmanism the life of the labourer is the property of the chieftain, and at his nod the head of the serf rolls at his feet. In these lands no Sabbath bell calls the peasant or the prince to worship, yet religious freedom is unknown, and religious toleration is only grudgingly granted where the bayonet of civilization is a terror to the pagan ruler.

"That same civilization which gives us the 'Higher Law' which lies at the bottom of all our legislation, gives us also the Sabbath. That same legislation which makes our lives and property secure, gives us also a day of rest—one day in seven—during which, save necessary labour, our time is our own. That same civilization which makes woman the peer instead of the slave of her husband, demands of her that she observe the Sabbath herself; and for the general good as well as for the special benefit of her own household, that she teach her children to do so likewise.

"Does it not seem strange that while admitting the benefit to the nation which observance of the Sabbath confers, so many of the component parts of that nation claim the substitute right to violate law made specially as a natural benefit? Will the most rabid anti-Sunday-law man stand up before the world and advocate a return to the habits and customs of the peoples who have no Sunday? In our land, to-day, the Anti-Mormon feeling is almost unanimous: there is scarcely a man in these United States who dares to advocate

polygamy; yet, except in countries where the Sunday is observed, polygamy is the rule. The same Christianity that gave us the Sabbath is the only form of religion that protects woman from seeing a second wife supplant her in her husband's affections; from being cast off in her declining years for one more youthful; and left by her natural protector to shift for herself just when her ability to protect herself begins to wane, her strength having been expended in her youthful devotion to him and his interest. It seems to me that obedience to the Sunday laws is a small price to pay for the liberties we enjoy.

"Christ himself says, the Sabbath was made for man, not man for the Sabbath; therefore it seems to me that, aside from the religious view of the matter, we ought to be thankful that God in his wisdom gave it to us, and that our law-makers accept the gift and secure it against the grasping greed of those who would, if possible, rob the labourer of even the one day in seven which sanitary experience proves to be an absolute necessity to physical health and vigour.

"I belong to a society composed entirely of old soldiers. A discussion about shooting arose one evening, and we resolved to have a shooting match. It was moved and seconded that on next Sunday we go out and prove our skill. One old man got up and said, 'I want to try whether my eye is as true as it used to be, but if you decide on Sunday, count me out.' A young man rose and said, 'Comrades, I am an infidel, and I don't care who knows it, but a decent regard for public opinion prompts me to say, if this shoot is to take place on Sunday, count me out.' 'And me,' 'And me,' 'And me,' came from all parts of the room, until the mover withdrew his motion, and a week day was decided on. Now, sir, a decent regard for public opinion ought, in my opinion, to be sufficient warrant for the closing on Sunday of every gallery in these United States, whose people 'by a large majority' respect the Sabbath, and disapprove of the violation of the Sunday laws."

Putting aside entirely all theological consideration as to the right or wrong of Sunday labour, there are other considerations which, in a community such as that formed by photographers, should operate in checking Sunday trade. As the majority of the community tacitly agree to abide by the law of the land and the practice of society, ceasing from business operations on Sundays, all should so refrain as a point of honour. For one man to open his studio is certainly stealing an unfair march upon others who respect the laws of society. Quite apart from religious scruples, it is clearly a mean proceeding to seek this advantage over others whose abstinence from such work is prompted by estimable motives. Photography is, moreover, an absorbing and exhaustive occupation, and if any class of workers needs the seventh day surcease from the mill-round of daily toil, surely the photographer does. We believe that it would not be difficult to show that no real gain is secured by an unbroken round of toil unrelieved by a seventh-day's interval of rest and change, for soothing intercourse with nature, beneficial study of nature's higher laws, and attention to those considerations which raise a man above the carking cares and grovelling aims which belong solely to the earthy part of his nature.

FRENCH CORRESPONDENCE.

INTERNATIONAL EXHIBITION OF SCIENTIFIC WORKS APPLIED TO MANUFACTURES.—LECTURE BY M. CROS ON COLOUR IN PHOTOGRAPHY.—MEETING OF THE CHAMBRE SYNDICALE DES PHOTOGRAPHES.—UNIVERSAL PHOTOGRAPHIC DIRECTORY.

PHOTOGRAPHIC operations, in general, are suffering from the effects of the season—the season, that is to say, indicated by the almanac, for its actual condition is such as to make us doubt whether we are not rather in the middle of autumn. The rain falls without cessation, and

the temperature is so low that we cannot make up our minds to assume the observances and dress suitable to summer. But inviolable custom imposes on us, whether or no, the necessity of "going out of town," and the idleness due primarily to really hot weather has now become habitual during the months of August and September. The last meeting, for the season, of the Photographique Society of France will be held on the 1st of August, and afterwards we shall all be taking our vacation, during which there will be very little news to communicate. There is, however, among us plenty of ambition to take advantage of, and to pursue the improvements which have been recently introduced into photographic processes, and the momentary stagnation will be followed in a few months by renewed activity, so that there will not fail to be a mass of interesting and important discoveries to record.

International Exhibition of Scientific Works Applied to Manufactures.—I may mention, in passing, the inauguration of an International Exhibition of Scientific Works Applied to Manufactures, which has recently been opened at the *Palais de l'Industrie*. Perhaps the term international is scarcely to be defended on the score of the number of foreign exhibitors; in perambulating the Exhibition, which is open to the public, though still in an incomplete state, I was struck by the small number of names affixed to the objects exhibited which are not those of Frenchmen. The section of Photography itself is very sparsely represented, and contains only a couple of dozen to thirty exhibitors; of these, there are only two foreigners—Mr. Woodbury, of London, and Herr Ganz, of Zurich. Moreover, there is nothing exhibited sufficiently important to be worthy of special mention, except it be the exhibition of the French Platinotype Company (the Willis process), of which the managing director in Paris is M. Stebbing. This is the first time that impressions in platinum have been publicly exhibited in France, and, for this reason, the circumstance appears to me to be the most interesting and noteworthy in our special section. Naturally, I can readily believe that immediately after the International Exhibition of 1878 there are very few persons who are disposed to make another display of their productions. The object of those who organize an exhibition of this kind is rather to establish a market or bazaar in a place to which the public has frequent and easy access, than to give occasion for an important industrial competition, or to stimulate further progress by a comparison of exhibited works. Not that I wish to criticise adversely the undertaking; it has its uses, and is capable of rendering good service in facilitating commercial transactions; I can therefore give it my full approval. But I think it only right to distinguish its special character from that of other exhibitions, whose objects are theoretically more important. Besides, I have myself the honour of being one of the organizers of this exhibition, and that is sufficient to show clearly that anything I have to say about it must not be taken as an unfriendly judgment.

Lecture by M. Cros on Colour in Photography.—M. Cros has recently delivered a lecture at the hall of the *Boulevard des Capucines* on the subject of the natural colours in photography. I was not present at the lecture myself, and can therefore only repeat what was told me by one of the audience. This gentleman, although a very intelligent and highly educated man (he is the author of some well-known works on art), brought away a very curious idea of the subject of the lecture: he thought that by the process of M. Cros the natural colours themselves are reproduced, and that there is nothing further necessary than to superpose these colours printed directly by photography. Great, therefore, was his astonishment when I told him that M. Cros could not have made such a statement, nor have wished it to be believed. I further informed him that M. Cros's system consisted simply in taking three

monochromatic negatives of the same subject, each one producing the actinic effect corresponding to one of the three primary colours—blue, yellow, and red: and that afterwards these three negatives are used for getting three monochromatic plates of those colours, but that the colours employed are selected from ordinary pigments, the same as those used by painters or for chromo-lithographs. "But, I assure you," he kept replying, "that is not what I was told." Evidently my friend had not understood M. Cros. Still, the result of the manner in which the lecturer expressed himself seems to be that his audience was carried away with the notion that there is a direct impression in colour, and believed in the possibility of reproducing photographically in colour the real colours of nature. M. Ducos du Hauron goes just as far when he calls his process, which is very nearly the same as that of M. Cros, Natural *Heliochromie*; this gives the finishing touch to the misconception. Besides this, if what I have been told is true, M. Cros wishes to make a position for himself at the expense of some of his colleagues, and principally of myself, and he is reported to have gone so far as to say that a southerner had succeeded in capturing the confidence of one of the largest manufacturing firms, &c., &c.; and by the southerner he means me. M. Cros is quite at liberty to attack the processes of his colleagues, and to call them all manner of names; he has a perfect right to do so, just as much as I have a right to declare that his system of working with three colours is chimerical, and to point out that it is false in theory, and unreal in practice. But why should he go beyond that point, and venture on personal imputations, whose least defect is their inaccuracy? And why does he employ arguments the principal effect of which is to rebound and injure the person using them? For my own part, I am too much above invectives of this description to take any great heed of them, and if I mention them, it is not from any feeling against M. Cros, who is probably ignorant of the scope of the falsehood of his accusations, but on account of the public, before whom a charge has been made which it might be inclined to believe, if I were to pass it by without notice. I can well understand the secret invitation caused by my frankness in telling the truth to the public without heed of any petty jealousies, even when the question is as to the laborious and, no doubt, well-meant efforts of M. Cros on the one side, and of M. Ducos du Hauron on the other, to induce the public to believe that they have solved the problem of the reproduction of the natural colours by photography. They speak with a conviction which I have no right to suspect; at the same time, my own conviction remains unshaken, and, without doubting their honour, I maintain that they are endeavouring to establish an unparalleled error, and that they are in a fool's paradise of their own making. But why do they seek to draw a parallel between their processes and (too great an honour for me) my method of applying photography to mechanical printing in colour—*photochromie*, as I have called it? What connection exists in their opinion between a simple combination of the photographic image by means of several impressions in various colours superposed on one another, and their process of reproducing the natural colours? Now, if my method, which is in substance merely an industrial application of photography, displeases them, if they believe it to be bad, and that no successful object can be attained by it, I do not think that they are unjust in saying it; nay, more, they have a perfect right to do so. But they exceed the limits both of law and of justice, as well as those of propriety, when—as I have been informed on good authority they do—they make an attack on the person, instead of confining their criticisms to the thing. I hope I have too much proper respect for myself to follow my honourable opponents in such a path as this; and I wish to close the discussion at this point. I will only take the opportunity of mentioning that I have in preparation an important work, to be published by M.

Gauthier-Villars, on the subject of colours in photography and on photochromie. In this work I have included all the evidence, and an account of all the facts, bearing on this interesting subject; it is illustrated with plates, and contains also a refutation of the theory on which rests this famous *Heliochromie naturelle*, which is no more a solution of the problem under consideration than any other artificial means of producing coloured photographs. This solution, so earnestly sought for, is still in the womb of the future, and however interesting may be the experiments and investigations which have been hitherto undertaken—and those of M. Cros are not the least among them—I cannot permit it to be said that they lead in the slightest degree to the end wished for. But, as will have been observed, I only combat against his system with the arms of courtesy and fair play.

Meeting of the Chambre Syndicale des Photographes.—Here we have nothing theoretical—nothing which touches on the technical part of the profession in which we are engaged; the *Chambre Syndicale de la Photographie* is an association of professional photographers formed for the protection of the interests of their occupation, and for the mutual study of those industrial questions which have a common interest for all. Another object of the Association is to take every means of defending the profession against all hostile attacks, and to bring collectively to the notice of the Government all those points on which photography can be of public advantage. These objects, it will be admitted, are such as should receive general support, especially in a country where the profession of photography includes so large a number of adherents as in France; it is reckoned that in Paris there are about 2,000 photographers, and about the same number in the provinces. Now the number of members of the *Chambre Syndicale* scarcely reaches 50. Among all the other members of the numerous body of photographers there appears to prevail a kind of indifference on the subject of the future of their art. They do not seem to care in the slightest degree for having a voice in the passing of laws which may affect the whole of the profession—for putting any pressure on that branch of the legislature which is considering the question of the extent to which photographic materials should pay duty—for appearing before the committee to whom is referred the subject of artistic copyright. Among ourselves the spirit of co-operation is very far from being so strong and general as it is in England; everyone is ready to throw upon others the burden of defending even his own nearest interests, and there is generally a want of the spirit of good fellowship. It may be said that, because a colleague is also a rival, therefore there is no reason for combining either for common defence or for common intention. But, it should be retorted, it is just in the name of a common interest that all forces and ideas should be united, instead of each acting alone on his own account. All this was said at the meeting by M. Berthaud, the honourable president of the Association, and resolutions were adopted having for their object the overcoming of this want of interest on the part of the majority. The questions which are pressing for immediate solution were entered on the agenda list of the next meeting, and especial attention was drawn to the regulation compelling every photographer authorized to take copies of the public documents in the State libraries to furnish the Government with a negative of each work thus copied. Most decidedly this appears to be an exaction, and had a committee of the more important members of the profession, representing the whole body, been consulted by the Government when the law was drawn up, it would have certainly prevented the introduction of a clause whose least consequence is a direct attack on artistic copyright. Questions of this kind surely affect the interests of the profession as a whole, but they would hardly come within the cognisance of a purely photographic society which is more especially devoted to the

management of technical improvements in our art and to the furtherance of new applications. It is much to be desired that there should be a means of presenting to the public the more official side of our profession; the photographic art could scarcely fail in consequence to gain in importance and practical utility.

Universal Photographic Directory.—Dr. Hornig, the distinguished and respected President of the Photographic Society of Vienna, has just published the first edition of a directory professing to contain the addresses of all the photographers in the civilized world, arranged alphabetically under the heads of countries and sub-heads of towns. Of course, at present, it is in an incomplete condition; and the Editor can only hope to make so large a work perfect by obtaining a co-operation of all those who are interested in its accuracy. A number of copies of this directory ought to be deposited at the places of meeting of all the photographic societies, and at the offices of all the photographic journals, so that there might be an opportunity for the correction of errors and the rectification of omissions. Dr. Hornig's work will, no doubt, be of great value; it is international in the highest sense of the word, and, for this reason, every one who is in a position to supply information necessary to make the work complete should at once do so. I feel convinced that any information of this kind that may be furnished to the indefatigable Editor of the PHOTOGRAPHIC NEWS by any of its readers will be immediately forwarded to the author of the *Universal Photographic Directory*.

LEON VIDAL.

PS.—At the instant of concluding this letter I have received the number of the PHOTOGRAPHIC NEWS for the 25th July. The subject of the lawsuit between MM. Liebert and Pierre Petit, as to their respective rights in the use of the electric light in photography, appears to me to have now been sufficiently discussed, and I do not think that there would be any advantage in saying anything further in reply to the very courteous explanation that M. Versnaeyen has been good enough to make.

GUP.

"TO-MORROW, and to-morrow, and to-morrow," has indeed been creeping on with petty pace from day to day, for many a long week past. "The rain it raineth every day," has been the universal cry, and the *Thunderer* has had ample scope to vindicate its awesome name by forecasts in which thunder, lightning, and rain have been variously recurring like bells in a harshly jangling chime. In spite of all attempts to lessen the ills of bad weather, the consequent depression of trade must have told sensibly upon the pockets of those to whom photography means daily bread. Amateur landscapists, too, have had their hardships. For what can be more intensely aggravating than to be interrupted, while adjusting the focus, by the premonitory drops that herald a down-pour? And, Oh! the weariness of developing a negative which ought to be all brilliant lights and shades, and which, naturally enough perhaps, turns out a dull mass of flatness, instinctively reminding one of a soiled handkerchief with holes in it, or of some other equally inspiring object.

But the weather is improving at last, at any rate, in my "parts." Moreover, with provoking inconsistency and utter disregard for constitutions that are not cased with steel and lined with sheet iron, it has run into extremes. The sun is a highly commendable institution, but the practice of dancing suddenly up and down the thermometer, like a monkey on a stick, is shattering the kaleidoscopic system, however much it may be improving the kaleidoscopic negative.

I suppose photographers are beginning to look about them for subjects for the autumn exhibition. I trust the

latter will not be ruined by the Sydney International, as it was last year by the Parisian. After all the progress that has been made in rapidity, and other branches, I think the Photographic Exhibition of 1879 ought to contain something startling. Mr. Laws' gas-light portraits ought to be on the line, as well as Mr. Symons' photograph of the mirage, and a frame of Messrs. Wratten and Wainwright's boat-race pictures.

On dit that Messrs. W. and W. are shortly about to introduce gelatine plates that are to be fifty times as rapid as wet collodion ones. I am debating whether to order a photographic binocular, or a photographic pea-rifle with an electric trigger. A farewell ode to my patent camera and rapid rectilinear is awaiting inspiration.

Talking of remarkable pictures, peradventure there are some of my readers who have never heard of the famous Indian tiger picture. This is how it came to be taken. A gentleman was photographing a cave, and, after due exposure, took away the plate to be developed. On development, he was astounded to find in the negative not only a picture of the cave, but also one of a tiger glering in the most naturally ferocious fashion from the mouth of the cave. It seems probable that at the moment the operator was exposing the plate—and, perhaps, bending his head to consult his watch—the tiger passed by, glared at the intruder, and, perhaps, not considering him a sufficiently digestible morsel to "force sweet appetite," made tracks before the photographer became unpleasantly aware of his vicinity.

I should have liked to have been that photographer!

Some little time ago I meandered through Messrs. Howell and James' art pottery galleries, and was much interested, if not instructed, by their graceful contents. It has struck me that a photo-ceramic gallery, if really well conducted and well advertised, would be a great success. Don't you think that this is an idea that might be made to bring forth fruit—eh, Mr. Henderson? Would not foreign enameillers contribute goodly exhibits, and could not fashionable London be educated up to the buying point? Society would be mad to possess a Mrs. Langtry tea-cup, a Maude Branscombe saucer, or a slop-basiu embellished with a full-length picture of Mr. Irving. There might be an æsthetic bar for American drinks attached to the gallery, and photo-tessellated with portraits of Sir Wilfred Lawson.

Diavole typographique, you are a sad little imp to prune my period and misinterpret my copper-plate "copy" with the misguided recklessness you betrayed last week. To read "capable" for "palpable" is a playful and maybe pardonable eccentricity; but "even" for "ever" is like sitting down on a tin-tack unawares, a perceptible, yet not altogether convenient, mistake.

Some one has sent me a catalogue of a Photographic Artists' Co-operative Supply Association. Personally I do not intend to desert my ordinary dealers in order to save a half-penny on an ounce of this, or three-farthings on a pint of that, or a penny on a dozen of the other. But there are others, perhaps, whom co-operation does interest, and who are willing to hear a few lines of "gup" on the subject. The P. C. S. A. is located at the former premises of the Uranium Dry Plate Company, in Goswell Street, and professes to do anything or everything in the photographic line. It makes a speciality of lenses, and gives an imposing chemical list. The chemicals are mostly those of Messrs. Hopkin and Williams, and the reductions are hardly—if at all—worth mentioning. One item deserves notice, namely, Schering's celloidin, which we have not remarked in any English dealer's catalogue as yet. Photographers may be pleased to know where they can obtain this undoubtedly valuable article. For the rest, photographic dealers and manufacturing chemists will have little

to fear from the apparition of the co-operative goblin amidst their hitherto unbroken ranks. To me photographic dealers have always appeared the most reasonable of traders.

I don't know much about the whole concern; but I think where gentlemen begin to play at shop-keeping, the sooner they drop the Esquire, and assume themselves to be called plain trader, speculator, or any other name that denotes their real occupation, the better.

If, however, photographic co-operation is to exist, why not have a co-operative society to prepare and develop customers' plates—aye, and to expose them as well? What a boon that would be to some not altogether unknown to

KALEIDOSCOPE.

Correspondence.

PHOTOGRAPHY AS A BUSINESS.

DEAR SIR,—The relationship that exists between an employer and his assistants is a question of some moment when we are considering photography as a business. I was not thinking particularly of this one matter when I wrote my last to you. But as your correspondent "George Bradford" has broached it, I may as well treat of it now as later. I am not willing to come to the conclusion that business principles among photographers have a lower standard than they have among other tradesmen; but I am sorry to say I feel rather shaky about it at times. That there is a great crowd of worthless unprincipled employers is as true as that there is a great crowd of worthless unprincipled assistants. It would be difficult to find a respectable assistant of ten years' experience who had not at some time suffered insult and injury from some such man as your correspondent tells us had him in Exeter. It would also be hard to find a respectable employer who has not been put to great trouble and inconvenience through the bad conduct of troublesome assistants. I was myself had last year by a low-minded, unprincipled fellow in the same city your correspondent dates from, but it is no use talking about such. We dare not publish their names, and such men as the one who insulted and robbed me care little what we think of them so long as their conduct pays them.

Yet I have very pleasant recollections of the beautiful city of Bath, as after I got clear of this fellow I went straight into the employ of a gentleman in the same city who treated me like a gentleman, and when we parted gave me his cordial good wishes for my future welfare. It is for the sake of such as him, as much as in the interest of my fellow-assistants, that I am writing, fairly and impartially bearing in mind the interest of both parties. I will endeavour to show how the good men may best avoid getting entangled with the bad, also what is the duty of each party respectively to the other.

When an employer wants an assistant it is to his interest in most cases to advertise for him, in preference to replying to the assistants who advertise for a situation, because he is sure to have a number of applications to select from, and it is strange if he cannot find one applicant who offers reference to some good house that he is acquainted with. He should give the preference to a man that has served his time in a good house, and if he wants an experienced man, he must select one that has been through some houses besides the one he served his time in; and when he gets a man who suits him, both in ability and temperament, give him a fair salary, and endeavour to keep him. Don't discharge him as soon as the days begin to get a little short and trade slack; this is a most unjust and cruel thing to do. What is the man who has served you well and suits you to do during the winter, if you, who know his worth, cannot keep him on? He has not much chance to get a situation among strangers at that season—has he? There is lots of work about a photographic establishment that a spare man can do during the winter. You are always wanting changes and alterations of some sort made

—backgrounds, accessories, and blinds all want looking to. The winter is the time to do it, and your own men are the men to do it, instead of leaving it over to the spring, and getting in a cabinet-maker to do the work, who will probably want you or one of your assistants to stand by him all the time, to show him what it is you want. In the winter you must push your business, make work, go in for enlarging and copying, introduce novelties that you have no time to attend to during the summer, and so manage to keep your assistants employed; and when the spring comes round, it will certainly be a comfort to you to know that you have got everything in proper working order, and good men round you that you can depend upon, instead of having to try new hands, and probably being annoyed by two or three duffers before you get one to suit you. Mind you, if you have discharged a good man in the autumn, and left that poor unfortunate to shift for himself during the winter after having worked hard and served you well during the busy season, it serves you right if you have some trouble to get another good man when you want him.

As regards salary, it is directly to the advantage of both parties that it should be a fair and just remuneration for services. If an employer engages a man when he—the man—is hard up, he may easily induce him to accept a lower salary than he is really worth; but he may be sure that he will leave him as soon as he sees a chance of bettering himself. Well, if you find the man is right and suits you, give him a fair salary; don't wait for him to ask you. Let the man know that you appreciate his worth, and if you are paying him the same that you believe anyone else who knew him would pay, there is no chance of his leaving you, because everyone knows that shifting about from place to place is a losing game. The salary should be just what will make each party feel independent of the other. The employer should feel that he is paying the man a fair price for his time and ability; the assistant should feel that he is getting a fair price for his work, and that he could get as much from any other employer who knew him.

What is the result? Each is independent of the other; but as it would almost surely be some loss and inconvenience for both to part, they will study one another's interests.

Of course, these remarks can only apply to good employers and trustworthy assistants. About the others I cannot say much. But I will tell you what appears to me the best way to decrease their numbers: that is, try to shut up the little establishments. A house that cannot find employment for an operator, a retoucher, and a printer, is not much good to anyone, either principal or assistant, and the quicker it is shut up the better. Such a house will keep two or three young ladies and two apprentices, besides a boy or two, and can get through an amazing amount of work easily. I assure you the boys are quite an important part of an establishment. They can save a great deal of a man's time; they can do the running about much easier than a man can, and leave him to his more important duties. It is the duty of every employer to keep a proper number of properly bound apprentices: if not, where are you going to get your tradesmen from? You don't want to have to rely upon men who have picked up the business—do you? I think you have done that too long.

I do like to see an advertisement for an operator "who will not object to make himself generally useful;" that means clean the plates, clean the dark-room, and, probably, the studio too.

Now an operator should be able to do all this, and to take a turn in the printing-room too, if necessary; but the employer who is foolish enough to pay a man to do boy's work should direct his abilities into some channel where there is no call for mental capacity. I don't wish anyone to suppose I put printing down as boy's work. It is too often left to boys to do, but it should not be. The head of the printing department should be a clever, able man, and is worth just as much as the chief operator.

I am afraid of making this too long for insertion in your

columns, but I cannot close it without saying a few words to assistants, but I will cut it as short as possible. When an assistant is looking for a situation he must avoid the little houses that I have spoken of; they do not pay the proprietor, consequently he cannot pay his assistants a fair salary. These are the sort of employers who advertise in the spring for an operator who can retouch. "A permanency for a suitable man." He will work you for three or four months, probably; he will want you to do everything, from dusting the studio and cleaning plates to a "little spotting in your spare time," day after day, as hard as you can go, driving all the time, until the short days come round, when, somehow, he will discover that you are not just exactly the man to suit him. Avoid them. Avoid the employer who is advertising about every two months for an assistant, and the man who does not put his own name and address at the bottom of his advertisement. When you get into a good situation with a good man, try to keep it, study his interest fairly, push his business for him to the best of your ability, maintain your rights and position, but don't hesitate to turn your hand to any work which may not be exactly in your department in a case of emergency. Don't scowl if there is a sudden rush of customers at dinner hour, neither make a practice of missing your dinner. In a house such as I have spoken of as a fair medium sized establishment, one man can always get away for half an hour, because someone else can take his place. Don't grumble to work an hour late at night now and then if necessary; neither make a practice of working late every night. Recreation and relaxation are just as necessary to a man as work is. I don't like to see a man make straight for his hat when the clock strikes six, leaving his work just any how; but if it comes night after night that you cannot get through the work in a fair day, your employer wants another assistant—tell him so. When you come across an unprincipled man, whether employer or assistant, cut him: don't recognize him as a fellow tradesman. I must leave off now, though I have not nearly exhausted the subject.

MASE.

SIR,—I addressed a few words to my brother operators two weeks ago, advising them to join, unite, and defend themselves from the octopus embraces of bogus employers.

A master has answered in strong, very strong, and intemperate language. He slings mud right and left with a recklessness that smacks of desperation. Wherefore all his passion, if he is a "good man and true?" "Let the galled jade wince; our withers are unwrung!" Let him read my letter over again, and he will find that I did not address myself to *would-be* operators. I spoke to good and clever men—men who wish to meet with good and conscientious masters; and, in my estimation, the aim of my last letter points at being of as much service to the master as the man. I likewise would add, that I never intended to take away anyone's character. The employers I alluded to have never any to lose.

With regard to the abusive language in "Exonian's" letter, I treat it with the contempt it deserves.—I am, yours respectfully,

GEO. BRADFORD.

Proceedings of Societies.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

June Outdoor Meeting.

THE first outdoor meeting this session took place on May 18th to Farleigh Castle, beyond Limpley Stoke, Somersetshire. The assemblage took place at the Clifton Down railway station, Bristol, from whence the Association proceeded by train to Bath, being met by the members of the Association who reside there. A brake was in waiting, and all the "wet and dry" paraphernalia having been stored away, the journey was continued, the camera stand, legs, &c., appearing here and there "promiskis like," as Mrs. Brown terms it, causing a certain amount of curiosity and wonder in the otherwise proper and sedate Bathonians.

The weather, which, early in the morning, threatened to "work the wet process," seemed quite to realise the fact that a "dry process" day had been arranged for, and so in an amiable manner determined to act in concert, the result being that, apart from a rather conspicuous presence of Boreas, the weather was delightful.

After leaving Bath, beautiful scenery was almost immediately entered; and, after driving for some miles, a halt was made at a most picturesque and fine aqueduct, over which the Avon and Kennet canal flows. Cameras, stands, changing boxes, &c., soon seemed to spring into existence, and some plates were exposed on a very pretty subject, being a lock, lockman's cottage, some very pleasing foliage hits forming a background. The wind proved itself very troublesome, but the majority of the members working with very rapid gelatine plates, a good many "shots" were made during a moment or two of calm.

The journey being again continued, none could help thoroughly enjoying the richness and varied character of the country through which they passed. At Limpley Stoke railway station another member was picked up by pre-arrangement, and with that ever lively sort of freemasonry which exists amongst amateurs, a gentleman, formerly a member of the Liverpool Society, accosted one of the members, and, after a pleasant chat, wished us hearty success. Arrived at Farleigh, the Rev. H. Hare, being well acquainted with the district, kindly volunteered to act as guide.

Everyone now seemed to "mean business," and many most charming "hits" were at once selected. The ancient and picturesque castle was at once visited, the chapel attracting very much notice. This is kept intact, and is adorned with a large number of suits of chain and other very old and fine armour, besides an original autograph letter of Oliver Cromwell in a fine state of preservation, of which one or two successful negatives were obtained.

Here a few plates were left to expose (it being an intensely dark subject), while the "wet process" with "beer preservative" was most successfully worked by the members pretty generally, bread and cheese, &c., being found very conducive to effective "density."

Farleigh House, a very quaint and pretty watereress farm, and other attractive subjects, were subsequently taken (old Boreas having retreated and allowed tolerable stillness to exist), and so time wearing on, a reluctant return to the brake and refreshed steeds was made, and a delightful country drive brought the party to Bath, where Mr. R. Biggs, deputy-coroner for west Somersetshire, most kindly invited the Association to form itself into his jury, using his dining room as its chamber while deliberating around his hospitable board. A verdict was very shortly arrived at unanimously, which was to the effect that "Mr. Biggs was a jolly good fellow from natural causes." It is, of course, quite unnecessary to state that the "jury" sat on nothing more tragic or doleful than chairs.

The Association (with the exception of the Bath members) then returned to Bristol, the unanimous expression being that a most enjoyable day had been spent.

July Out-Door Meeting.

The second out-door meeting for this session took place on Wednesday, 23rd inst., the place selected for visiting being the private glen at Blaize Castle grounds, which Mrs. Harford kindly placed at the Association's disposal. The meet took place at the Clifton Down station, and as it was understood that "wet plate" work would be the order of the day, the boxes, &c., presented a rather bulky, but nevertheless determined, appearance. All being ready, a start was made, and after a three-mile drive across the splendid Durdham Downs (the property of the Bristol citizens), and through the pretty village of Westbury-on-Trym, the eastern entrance to the richly wooded and beautifully undulating Blaize Castle estate was reached.

After passing the two gate-houses (where the party's credentials were solemnly inspected by an old family servant) the brake descended the winding drive which leads to the private glen.

The Hon. Secretary, having had the privilege of a couple of days' work there before, knew the geography of the place, and his advice being taken, the traps were deposited.

The day looked as if meaning to turn out all that could be desired, the sun shining most brilliantly, with here and there a fleecy cloud to temper its harshness, and everything looking bright. Here, then, under the shadow of Giant Goram's Chair, and the Lover's Leap, with the picturesque pool and its water-lilies and ivy-clad bridge at their feet, the members pitched their

tents. But alas! the first camera had not been placed in position and the exposure commenced, ere groans and lamentations were heard on account of the gradual but sure increase of wind. An hour or two were soon employed, however, in "spotting" suitable bits, which abounded when the time approached for the trials to be made, most of the subjects being those for afternoon light.

Most members seeming to possess some remarkable instinct as to the approach of lunch time, all were soon assembled. One member who had been lost to sight, to memory dear, for a couple of hours, appeared with a most effective and pleasing oil-colour sketch of a cascade in a part of the grounds, seeming determined not to waste time, although the wind did seem bent on being unfavourable.

After lunch, several plates were exposed, both single and stereoscopic, from the latter size to 12 by 10, both by the dry and wet process, and it was quite evident that the former (gelatino plates) had a great advantage over the latter, as far as windy days were concerned, full exposures being quite possible just between the puffs of wind. As the day wore on, however, the wind grew too boisterous for photographing, some members having stood at their cameras more than an hour trying to get spoils of a few seconds' stillness to make an exposure, and after all being unsuccessful and giving up in despair. Disappointment was depicted in every face (except that of our oil-colour friend, who certainly had the best of it) and amid lamentations (and I fancy I heard stronger vernacular), packing was commenced, very few negatives indeed having been secured. The atmosphere, &c., being perfect, it was felt to be most unfortunate that work had been so disastrously prevented by wind alone.

On the return journey an exposure was made with a gelatino plate by one member, the subject being a panoramic view of Westbury Village and adjacent hills. At the invitation of the Hon. Secretary, the Association returned to his house, where a more satisfactory and successful performance took place which was more agreeable to the body than the experiences of the day had been to the mind. Chatting in the evening over the coffee concluded what all wished had been a more successful day.

Talk in the Studio.

THE SILVER DEPOSITS OF LEADVILLE, COLORADO.—Says a correspondent of the *Boston Advertiser*:—"The ore beds vary from one to forty feet in thickness. They are generally undulating like the waves of the ocean, so that the distance from the surface varies with the undulations. The size of a mining claim is in most cases 300 feet inside by 1,500 feet long, being about ten acres in area. The ore known as "hard carbonates" consists of silver mixed with iron or lead. The soft or sand carbonates resemble common road gravel, yellow and red ochre and grey sand. Chlorides of silver are frequently visible in the hard carbonates. The usual size of a shaft is $3\frac{1}{2}$ feet by 7 feet, and is substantially timbered. After the ore deposit has been penetrated, the "main entry," "parallels," and "cross cuts," are excavated, leaving the remaining ore in blocks while the work of exploration is going on. In sinking a shaft we usually penetrate, first, a deposit of gravel or "wash" from 20 to 100 feet in thickness, frequently containing boulders which have been subjected to abrasion. Not unfrequently a stratum of "cement" a few inches in thickness is encountered, resembling Roxbury pudding stone or an old cemented cellar floor. Next we come to calcite, or porphyry—sometimes soft like "fire clay," either pure white, grey, or red—the latter showing an iron stain. The soft porphyry runs from one inch to several feet in thickness. The hard porphyry is often "picking ground" (i. e., porphyry rock, which can be excavated by means of a pick), but frequently it is blasting or "shooting rock." Following the porphyry is iron ore, varying in thickness and sometimes containing a few ounces of silver. Following the iron we find the "pay ore," more or less rich in silver. The generally accepted theory is, that this region was once covered with a lake, the waters of which held in solution silver, lead, and iron, which were in time precipitated on the bottom of the lake. The porphyry, gravel, &c., were subsequently deposited. After the precipitation came the age of disturbance, when by volcanic action or the shrinkage of the earth's crust the deposits became contorted, sometimes tilted or broken like a "chop sea," or gently undulating like the "ground swell" of the ocean.

To Correspondents.

R. S.—We should consider the present arrangement of your studio all wrong. The only glass you have not blocked up is, you say, on the south-west side. That is really the side where the glass would be better blocked up. We should make the studio five feet narrower, as you propose, and get your principal light from the north-east side, which should be clear glass. The ends should be opaque. If you work with a north-east light you will have no difficulty in working at either end of the studio.

J. T. B.—A silver-plated funnel will answer for filtering a gelatino-bromide of silver solution. But we should not recommend the use of any other metal.

IODIO.—We believe that Mr. Solomon keeps iodized paper for printing enlargements by development. There are various formulæ for preparing such paper, each declared the best by the person devising the formula and becoming familiar with its working. Here is a formula which gives, we believe, very good results: Water 1 ounce, iodide of potassium 2 grains, bromide of potassium 4 grains, chloride of ammonia 6 grains, gelatine 2 grains. The silver bath contains 50 grains of nitrate of silver and 2 minims of acetic acid to each ounce of water.

B. F. D.—Last year a small charge was made to non-members.

You will ascertain, when the circular of conditions is issued, all the details of arrangement for the next exhibition. Until last year no such charge was made; non-members, as well as members, were eligible as exhibitors at the forthcoming Exhibition of the Photographic Society, and were also eligible as competitors for the prizes offered. The conditions of membership in the Society are an interest in the art and the compliance with the rules of membership. To become a member you must be duly proposed by a member. The nomination having been submitted to the council and passed, the nominee is then submitted to the ballot in a meeting of the members, and elected. The subscription is one guinea annually, and one guinea entrance fee. We regret that extreme pressure of duty did not permit us to write. We shall have pleasure in proposing you as a member of the Society if you desire it. The next session commences in November next.

TRY HARD.—The defect known as "crapiness," of which you complain, is due to the presence of too much water in your collodion, or, in other words, to the use of ether and alcohol insufficiently rectified. It is probable that excess of somewhat weak alcohol has been used. Equal parts of ether, of a sp. gr. of .720, and of methylated spirit, sp. gr. .820, will generally give a satisfactory collodion; but if, as you say, you have used two parts of rectified spirits and one part of ether, the collodion will probably contain too much water. The collodion once made, you cannot remove the water, but you may use up the collodion by mixing it with another good sample. You may also, to some extent, modify the defect by letting the film set well before immersion in the nitrate bath.

D. W. H.—In our experience, collodio-chloride of silver prints, either on paper or glass, are permanent. For use on opal glass, collodio-chloride of silver should always have citric acid added. In printing with this preparation on opal glass we prefer to work on the glass itself without any substratum. Take dilute albumen, consisting of one part of white of egg to three or four parts of water, and apply an edging about one-eighth of an inch wide all round the glass; when that is dry, coat with collodio-chloride. Allow the film to set thoroughly. Then dry by a dull fire, and print as soon as the film is cold again. Tone in an old weak gold bath. Fix by immersion in a hypo bath, containing one part in eight, for five minutes; then wash under a tap for five or ten minutes. Plates so treated will be quite permanent. There are two causes for films splitting; one is the use of a very tough contractile collodion, the other the use of a collodio-chloride which has become somewhat decomposed with age.

M. M.—The advantage of the use of carbonate of lime in the toning bath for neutralizing any free acid in the chloride of gold is its insolubility, which prevents the solution dissolving excess of alkali.

PHOTOGRAPHERS AT EXETER.—A correspondent from Dawlish writes as follows:—"I have a fancy that the letter in the *News* of July 18th, from 'George Bradfords,' is a gross libel on the city of Exeter and the profession, for the following reason. A young man lately from London has taken a situation in Exeter, and thinking he would like to know who the employer was, sent a letter to the address given; it is just returned through the *Dead Letter Office* as not known." Our correspondent's reason is inconclusive, and his fancy not well founded. A libel must refer definitely to some one, or it cannot be a libel. The letter referred to carefully avoided personality or reference to any one who could be identified. The city of Exeter could not be in any way responsible for the acts of one of its inhabitants. The "young man" in question must have been very young indeed if he hoped to ensnare the writer of the letter into mentioning names, and so make his hitherto innocent letter really a libel.—Ed.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION. The address of the Association is 160A, Aldersgate Street.

The Photographic News, August 8, 1879

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

SUMMER TIME AND AMATEUR PHOTOGRAPHERS.

THE landscape photographer is at last blessed with fine weather, and the many gentlemen, aye and ladies too, who have been patiently waiting for summer to try new apparatus and the new extra-rapid gelatine plates, will not have lost their opportunity. It would be interesting to know how many amateurs there are in Great Britain who occupy their spare time with camera work; but that their number is legion is evident, if only by the large number of dry plates that are prepared and sold, and which find their way for the most part into the hands of dilettanti. We know this much, however, that the amateur photographers of Great Britain have made a mark for themselves, and that not a few of the improvements which we employ to-day are due to their practice and experience. Both in the science and art of photography, the gentlemen and lady amateurs of Great Britain can boast that they have in many instances been in the van. To cite the names of Russell Manners Gordon and Robert Crawshaw is quite enough to prove our words, while scarcely an exhibition at Pall Mall passes that does not contain the work of lady photographers: Mrs. Roscoe, Mrs. Huggins, Mrs. Annie Brassey, are well-known workers with the camera, and there are others not less ardent and efficient. Neither time nor money is spared to effect improvement in their results, and they are ever ready to make known the fruits of their experiences. In many respects the camera offers pleasant occupation. The charm of securing pictures of well-beloved spots, and the fact that a degree of attention and labour is necessary to performing the task with success, renders photography attractive to many who have no wish to idle away their spare time. One class of enthusiastic amateur is the traveller or tourist, one who knows that his work must be well done if it is to repay him for the toil and trouble involved in carrying an apparatus with him on his journey. He cannot afford to do things in a haphazard fashion, and must needs qualify as a capable photographer before he starts. He may lighten matters as much as possible by the adoption of dry plates, but it does not suffice merely to put these into the camera, and uncover the lens for a time, in order to secure good pictures. He must have an eye to artistic effect, and some experience in the choosing and modifying of foregrounds, in the vagaries of his lens, and, more than everything else, possess considerable knowledge on the subject of development. With dry plates, however, the amateur photographer certainly gets rid in summer time of more difficulties than those involved in the dipping bath. He need not give much attention to the subject of heat. There is no fear of the plate spotting, or becoming dry during its sojourn in the dark slide. Many ways have been proposed for getting rid of the liability of wet collodion to desiccate in the camera, and yet there are none that can be safely recommended to an amateur who is not well versed in manipulation. All preparations that have been proposed for application to the wet films have their drawbacks, and if wet plates are employed on a hot day, the simplest plan of keeping them moist is to put behind the glass a sheet—or, better still, double sheet—of filter paper soaked in distilled water. A measure of this kind does not affect the film, while the evaporation that goes on is sufficient to maintain the collodion in a damp and cool condition quite long enough for ordinary purposes. The re-dipping of a dried plate is also a simple way of getting over the difficulty; but many photographers do not like having recourse to such an expedient, for the simple reason that impurities may thereby be carried into the dipping bath; and to employ another silver solution on purpose is rather a costly mode of pro-

ceeding. The dry plate has therefore a considerable advantage over a wet one in summer, and it is in summer only that the amateur, as a rule, works. In the dull, cold months he leaves his professional brother in full possession of the field, and contents himself with improving his negatives or overhauling his apparatus. Let anyone who wants to know what amateurs can do, look at the prints annually submitted by the members of the Amateur Photographic Association to compete for the yearly prizes. The beautiful landscape scenes transferred to the sensitive plate are wonderful to behold, and they generally include pictures taken in nearly every European country. The amateur landscape photographer is, in nine cases out of ten, something of a painter or draughtsman, and the artistic training helps materially in the choosing of foregrounds and composing of pictures. A man who has studied picture-making does not allow square miles of dry grass to appear in his foreground, nor allow a wooden railing to run across the middle of his scene. He has always an eye for a rocky boulder with a tuft of ferns, a broken-down stone wall half smothered in ivy, or some still back-water with a huge water lily upon it. These are good subjects to compose in the foreground, and if a homestead and cottage thatch can be brought into a landscape, he knows it will at once stamp the picture with its nationality. Indeed landscape photographers, when they wish to record mountain, waterfall, vale, or glen, generally do well if they can secure some rustic tenements alongside the natural beauty, to give the same a distinctive character. The Tyrol chalet is to be distinguished from the Swiss, as a rule, by the highly-wrought wooden belfry that is seen in the former, while the mud cabin of the Irish peasantry is distinct from the cot of an English labourer. A Yorkshire hut of dull, grey stones differs, again, from one of brighter Kentish rag; and the whitewashed tenements of the German, with black squares and triangles traced outside, are not easily taken for houses in an Italian village, where many bear a painted fresco. Another point is that of securing pictures under favourable auspices, and here, because amateurs love their work, and are not pressed for time, they frequently succeed better than their professional brethren. We have before us, as we write, a charming little cabinet picture representing a scene in North Wales. The gentleman whose work it is essayed several times before he succeeded. In the foreground is the high road and a stone wall, with some sheep feeding by the roadside. There is a cottage beyond, and softly-outlined hills in the distance. The sheep are shaggy, and their wool is so soft and so clearly lined that you long to plunge your hand into the deep fleeces. The stone cottage is not very prominent, but its whitewashed front serves to light up the picture behind the sheep, and to lift them into prominence. Altogether the photograph is one of the most perfect we have ever seen. But in order to make it so complete, and secure the high light where it was, the picture was taken time after time, and in the end the photographer found he could not succeed to his satisfaction until he had taken the trouble to have the face of the cottage whitewashed, and thus avoid monotony in his landscape.

FRENCH CORRESPONDENCE.

NEW SECRETARY AT THE PHOTOGRAPHIC SOCIETY OF FRANCE—
M. LEON VIDAL'S IMPROVEMENTS IN TRAVELLING CAMERAS—
PAPER BY DR. VAN MONCKHOVEN ON THE PREPARATION
OF GELATINO-BROMIDE.

A LARGE number of the members of the Photographic Society of France have taken their departure from Paris to enjoy the pleasures and repose of life in the country; but they will regret not having remained to be present at the last meeting of the season on the 1st inst. This meeting turned out to be the most important of the session, chiefly in consequence of a communication by Dr. Van

Monckhoven on his new method of preparing gelatino-bromide emulsions.

New Secretary of the Photographic Society of France.—At the commencement of the meeting a change in the staff was announced by the President. M. Kosiell, who for a long number of years has discharged with great assiduity and intelligence the duties of Acting Secretary, has, in consequence of his being admitted a partner in the business re-established in Paris by M. Schembosche, sent in his resignation to the Society. In making this announcement, the President expressed the regret experienced by all the members of the Society at the loss of the late Secretary's services, and their great appreciation of their value, and M. Kosiell returned thanks in a few modest and appropriate words, upon which the President formally inducted the member who had been appointed to succeed M. Kosiell in the office of Acting Secretary.

M. Leon Vidal's Improvement in Travelling Cameras.—So soon as some of the subjects on the agenda paper not possessing any great general interest had been rapidly disposed of, M. Leon Vidal exhibited to the meeting a travelling camera into which he had introduced several valuable improvements. Chief among these are the removal of the ground glass plate, preserving at the same time the means of focussing with great accuracy, and an arrangement for reading exactly the size of the image formed on the sensitive plate as regards both its length and its breadth. These contrivances of M. Vidal will be found of great value to tourist photographers, who are often hampered by the wind in using the focussing cloth, and are prevented altogether from taking photographs if by any accident of travel their ground glass plate be broken. No attention has been paid to these special points in any of the portable cameras of which descriptions have been recently published, and for this reason M. Vidal has thought it opportune at the present time to bring his invention to the notice of the Society, although his description, which I give below in his own words, is merely a repetition of facts already known. As regards the arrangement for focussing, he said:—"The eye-piece, of which I show a model, is attached to a shutter which is adjusted to the back of the camera in the same place as is occupied by the external shutter of the slide carrying the sensitive plate. This eye-piece, combined with the objective of the camera, forms a regular telescope, by means of which distant objects are seen magnified and erect. To determine the exact position where the image would be depicted on the ground glass plate, a smooth glass plate, on which are traced with a diamond point several fine lines, is placed in the same grooves as are occupied by the ground glass. A view—or, better still, a page of printed type—is looked at through these lines, and the eyepiece is moved in its friction tube until the printed characters and the lines on the glass plate are seen simultaneously in exact focus. On the sliding tube of the eyepiece a mark is then made at the point where the outer tube ends, and this point is thus exactly fixed for all future focussing. It is true, only a part of the image is seen—that is to say, the central part—but in practice this is found to be sufficient." The arrangement adopted for determining the limits of the image in each direction M. Vidal describes as follows:—"On a wooden stage is fixed a graduated semicircle furnished with an alidada moving on a pivot at the centre of the semicircle, and carrying a reading scale at each of its extremities. A mark is engraved on the plate of the alidada raised above the exterior rim of the semicircle, the zero point being at its centre. By a previous trial with the ground glass plate the angle of vision of the objective is first determined, and when this is known it is only necessary to place the stage, either horizontally or vertically, on the walls of the camera, in order to obtain by a rapid glance the extension of the reflected image in every direction—to find its centre, its extreme edge, and

its height. For this purpose, the movable alidada must be brought on both sides of the zero point up to the degree indicating the half of the angle of aperture. The same stage or slide can carry both the eyepiece and the graduated semicircle. An eyepiece and a ground glass plate may be employed simultaneously, provided that a transparent space is made at the centre of the latter, as is shown in the instrument now exhibited. In order to be able, in case of any derangement of the eyepiece, to find the focussing point again quickly, I have covered the transparent space with very fine cross-lines drawn parallel to the sides of the plate at a distance of about half a millimetre from each other; the result of which is, that in looking across this network of lines, we have something equivalent to a plumb-line or a level, by which we can adjust the instrument so as to get all architectural lines in their correct positions; besides, the gradation in half millimetres affords a means of estimating with accuracy the dimensions which any portion of the image will have on the negative. By the aid of these appliances, the focussing cloth, as well as the ground glass plate, can be dispensed with; moreover, we can attain a degree of nicety in focussing, and a precision in the whole of the operation, which cannot fail of meeting the approval of all those who are anxious to meet with improved travelling cameras." This interesting and valuable communication, I may add, was received by the meeting with every sign of approval and satisfaction.

Dr. Van Monckhoven on the Preparation of Gelatino-Bromide Emulsion.—The meeting was concluded with a paper by Dr. Van Monckhoven, which the latter had entrusted to his friend, M. Leon Vidal, to read. It is so important and valuable that I have allowed no time to elapse before sending a proof for publication in the PHOTOGRAPHIC NEWS (see below), in order that Dr. Van Monckhoven's views may be known in England. There can be no doubt that those views will be welcomed in the photographic world as a discovery destined to exercise great influence on the methods of working with emulsions which are now so much in favour. Dr. Van Monckhoven, who was himself present at the meeting, added some verbal explanations as to the details of his process. More especially, he pointed out the exaggerated notions that are entertained of the part played by the gelatine in emulsion photography, while it is really to the molecular condition of the bromide that the rapidity of action is due. He showed also that the great care to obtain an absolute white film which is always insisted on is quite unnecessary, for, as he states in his paper, the green films are in reality the best. Another very important point, in his opinion, is the chemical analysis of the water used in the process, in order to remove from it all substances which may have an injurious effect. In private conversation, Dr. Van Monckhoven mentioned some artifices which he recommends to ensure success in working his process, and gave all the advice and information that was possible in reply to questions put to him. The meeting then broke up, after acknowledging gratefully the services which Dr. Van Monckhoven has again rendered to the photographic art, which is already indebted to him for so many beautiful discoveries. K. VERSNAEYEN.

ON A NEW METHOD OF PREPARING GELATINO-BROMIDE OF SILVER.

BY DR. VAN MONCKHOVEN.*

In order to make what follows perfectly clear, let me first shortly recapitulate the ordinary method of preparing emulsions of gelatino-bromide of silver. I will take the method of Mr. Bennett, as it serves for a type of all others. Take 20 grams of gelatine and 7 grams of ammonium bro-

* Read before the Photographic Society of France at the meeting of the 1st of August last.

mide, and dissolve them in 250 grams of water heated to 32° C.; then add 11 grams of silver nitrate also dissolved in 250 grams of water at the same temperature, and stir well. This mixture is allowed to rest for several days (always being kept at a temperature of 32° C.) or for a still longer time, in proportion as an emulsion is to be produced more or less sensitive to light. It is then cooled until it assumes a gelatinous consistency, well washed to remove all traces of ammonium nitrate and all excess of alkaline bromide which it may still contain, and flowed over the plates, which are then put aside to dry. The latter are exposed in a camera, and then developed by what is known as the alkaline method.

This process I have studied with great care, and have observed the following phenomena:—1. If at the instant of preparation the emulsion be flowed over a glass plate, the film will be seen to be nearly transparent, notwithstanding the presence of the silver bromide which it contains in a finely divided state. The film is white and opalescent; in looking through it the bars of a window or any other object which is strongly illuminated will be plainly distinguished. But if the plate be coated with emulsion the day after the latter has been prepared the film will be much less transparent, and if the emulsion be used a week after its preparation a perfectly-opaque film will be obtained. Of course, it is understood that the emulsion must be well shaken before flowing it over the plate. 2. On examining the colour of the freshly-prepared emulsion, it will be seen to be a milky white; but at the end of a week it will be found to have turned a distinctly greenish white. 3. When films prepared with emulsions in different states of emulsification—as described under 1—are exposed to the light, those which are fresh and are white and transparent will assume the slaty blue colour characteristic of the haloid salts of silver more quickly than the others. The older films, possessing a green tint, will scarcely darken any further on direct exposure to the light. 4. What renders this latter experiment still more curious is the following fact, which is, so to say, its antithesis. White films, which change most rapidly under exposure to direct light, are slower to receive an impression in the camera, while the green films, which scarcely alter at all in direct daylight, are incomparably more rapid in the photographic instrument. From the circumstance, therefore, of a silver salt blackening rapidly in direct light, it cannot be inferred that it will behave in the same way in the camera.

I have the honour of exhibiting to the Society prepared plates in different stages of emulsification. The first ones, marked No. 1, are white and transparent, darken quickly in the light, but are very slow in the camera; the others, marked No. 2, are of a green tint, and opaque; they do not become darker in the light, and are eight times as rapid in the camera as the former.

In order to obtain an insight into the phenomenon which I have above described, I submitted the bromide of silver in its different molecular conditions to a long course of experiment, of the result of which I will now give an account. Silver bromide exists in two states: * in the first, which we will call the ordinary state, since it is well known to chemists, it is obtained by pouring a solution of alkaline bromide into one of an excess of silver nitrate acidulated with nitric acid, and then well shaking. By this means there is thrown down a heavy precipitate, which soon lumps together; it has a greenish-white colour, and turns grey on exposure to the light. The other modification is formed by dissolving this green bromide in ammonia, and then adding an acid; a bromide of a white colour and milky consistency is thus obtained, very light, and passing with ease through the finest filter. But if this milky fluid be allowed to stand for some days, it will deposit at the bottom of the test-glass a white bromide, which may be

more or less easily collected on a filter, and this bromide, on being exposed to the light, assumes the violet tint of the haloid salts of silver. Lastly, when this white bromide is left to itself for a long time, it becomes heavy and granular, and turns a greenish colour—in short, assumes the molecular condition of the green bromide.

These facts go to prove that emulsification consists in transferring into the green bromide the white bromide which has been formed in the substance of the gelatine. The particles of bromide are at first of extreme fineness; they have a tendency to reunite with larger particles, and then pass into the state of the green bromide—not heavy and curdled, but fine. What also tends to prove this is the fact that the emulsion at first possesses all the characteristics of the white bromide: afterwards, when it has ripened, it has the same properties as the green bromide. The transparency of the film at the outset shows that the bromide is in a finely subdivided state. Later on the particles become larger, and hence the opacity of the film to light. In many cases, also, the particles are visible under the microscope.

Carbon, when subdivided, gives similar phenomena. Take, for instance, some lamp-black, and beat it up in a solution of gelatine. A little of this liquid spread in a thin film over glass appears at first opaque, but in proportion as the churning is continued and the particles rendered finer, the film will become translucent, and finally transparent. India ink, which consists of carbon so finely subdivided that there is no deposit from its aqueous solution, is quite transparent, if a thin film of the solution be examined.

If, therefore, my views be correct, the greater the facility offered to the particles of bromide to coalesce, the quicker will be the emulsification. This is what happens when ammonia is added, according to Mr. Bennett's formula; the addition of ammonia transforms the white bromide into green bromide in as many hours as it would otherwise require days. On the other hand, the addition of a few drops of sulphuric acid retards the emulsification. The latter is also effected much more rapidly in solutions containing a small quantity of gelatine than in those which are more concentrated. The former are more liquid and mobile, and consequently permit the fine particles of white bromide better to coalesce into the larger particles of the green bromide.

According to this theory of emulsification we can lay down the most favourable conditions for the preparation of gelatino-bromide. The great defect of Mr. Bennett's method, and of those which have succeeded it, is due to the decomposition of the gelatine during emulsification, and to the long time required for washing the preparation. When the gelatine has been kept hot for any length of time it does not adhere to the glass, or if it do adhere, it does so very slowly. It often happens, in consequence, that after developing, the whole film curls up, and even detaches itself from the plate. Disasters of this kind arise from the gelatine decomposing. Moreover, the operation of washing is outrageously long and tedious, and requires an enormous quantity of water.*

The following method avoids these inconveniences:—I prepare very pure and dilute hydrobromic acid, and I determine accurately the amount of it required to precipitate exactly 10 grams of silver nitrate. I then dissolve this quantity of acid in 200 grams of water, with which I incorporate by heating 2½ grams of gelatine. On the other part—and from this moment I entirely operate in the dark room—I precipitate 10 grams of silver nitrate by a very

* Captain Abney has recently made public a method in which he forms the bromide separately. He washes it, and then mixes it with the gelatine. He asserts that after a few hours the bromide is distributed throughout the mass. I have repeated this experiment accurately, according to the directions, and have also caused it to be repeated by others. On each occasion the film was completely granular, and full of large particles of the silver bromide, forming so many white points, which in the image were transparent. Time will show whether Captain Abney's method is practicable,

* In a subsequent note I intend to return to this subject and the observations of M. Stas on the same.

slight excess of bicarbonate of soda; I let it settle for twenty-four hours, and then renew the water to the same amount, after which I let it settle again previous to decanting. On this precipitate of silver carbonate I pour a hot solution of 2 grams of gelatine in 200 grams of water. This is well stirred, and then I pour on it the solution of gelatine and hydrobromic acid. The mixture is thoroughly shaken every quarter of an hour, and is kept at the constant temperature of 50° C. The silver carbonate dissolves slowly in the hydrobromic acid, and the silver bromide is formed in the colloidal liquid in a state of extreme subdivision. At the end of ten or twelve hours the mixture, when flowed over glass plates, has a greenish white colour. I next introduce 10 grams of gelatine, cut into very thin shreds, which I dissolve by stirring, and then, without washing the emulsion, I flow it over the glass plates.

In order to obtain a success with this method it is necessary to take some precaution. The hydrobromic acid must be free from phosphorus and sulphur; the water used for washing the silver carbonate must contain no trace of carbonic acid. This paper has, however, already exceeded its proper limits; I will, therefore, reserve the more minute details for a further note, which I intend to publish subsequently.

In an emulsion prepared by this method there is always an excess of hydrobromic acid and of silver carbonate, but I have satisfied myself by other experiments that the presence of these substances does not affect the results. This is not the case if carbonate be replaced by the oxide of silver; the emulsion is then grey, and gives rise to fogging. The plates that I have prepared by this method are twenty times as rapid as the best wet collodion, and, compared with the best English plates, I have found them to be three or four times as rapid. For the rest, the same observations and the same methods apply also to collodion-bromide.

ON THE USE OF BROMIDE EMULSION

FOR MAKING TRANSPARENCIES AND REPRODUCTION OF NEGATIVES.

BY JOHN CARBUTT.*

HAVING been invited by our friend Fitzgibbon to contribute something practical for his forthcoming "Practical Almanac," we give below our method of working the collodion-bromide emulsion process for making transparencies, either for magic lantern slides, decorative transparencies, or reproduction of negatives. It is for the latter purpose we chiefly employ it, finding it more certain, simple, and reliable, than the dusting-on process or carbon transparencies for that purpose.

In the making of the emulsion we have not much, if anything, new to communicate; but in the exposure and development, the all-important points in this work, a few notes from our experience may, perhaps, be of use to some who may for the first time essay emulsion work.

We recommend the unwashed emulsion; and if the reader will carefully follow our directions, we think he will find satisfaction in the result.

To Prepare Ten Ounces of Emulsion.

Alcohol, 95 per cent.	2 ounces
Double bromide cadmium and ammonium	90 grains
Cotton (Anthony's negative red label)	50 "
Ether, concentrated	6 ounces

We advise a larger quantity to be made in above proportions, and allowed to age before use.

To Sensitize.

Nitrate of silver	125 grains
Water	1 drachm
Alcohol	2 ounces

Put the alcohol in a two-ounce wide-mouth bottle, the silver and water in another two-ounce bottle; place both in hot water; when the silver is dissolved, add one and a half ounces of alcohol to the silver; keep in the hot water till silver is all dissolved; add it by degrees to six ounces of the bromized collodion, in a sixteen-ounce bottle; rinse out the bottle with the remaining alcohol, and add to the collodion; shake vigorously for a few minutes, and set away for two hours, then add two ounces more bromized collodion; after shaking up well, set aside for four to six hours; then test for free silver, by taking an ounce of distilled or ice water, and pouring into it about a half drachm of the emulsion; stir with strip of glass, and filter from the precipitate; into a portion of the clear solution, drop from one to four drops of plain ten-grain silver solution. If the emulsion is in correct condition, it will assume a faint opaline colour, showing a faint trace of free bromide, its *right condition* if no change of colour takes place; and if, on taking a fresh portion of the clear solution and adding a drop or two of a twelve-grain solution of bromide of potash, a change of colour takes place, it shows free silver in excess. This must be remedied by adding a few drops of an alcoholic solution of bromide of cadmium till the silver test shows free bromide. In this condition I find it to keep in good working order for months.

In preparing the plates, use as a substratum a solution of gelatine three grains to the ounce of water, and to ten ounces add two grains chrome alum; flow over the cleansed and moist plate as in using albumen.

Coating the Plates with Emulsion.—Shake the emulsion in the stock bottle, and strain into pouring bottle through cotton placed not too tightly in glass funnel; flow the plate with emulsion, and when set place in a dish of clear water. Several may be coated and placed in the water until the greasy lines disappear. Wash under tap for thirty or forty seconds, drain a moment, then flow over ale or beer that has stood some time to flatten; let the first application run off into the sink; apply a second portion, drain into cup, place the plate in a well varnished rack, in a light-tight box or closet to dry, either spontaneously or by warm air; when dry, place in grooved boxes.

Exposure and Development.—Lay a mask in the printing frame with an opening a little smaller than the negative to be copied; lay the negative on this mask, and carefully lay on the negative the prepared plate; cover with black or yellow paper; put in the back, and fasten down the cross-bars; carry out to the light (not the sky-light, but an ordinary sized window), and at a distance of three or four feet, uncover the frame for one to five seconds; return to the dark room, and place the plate in water for a few seconds. Have ready in dropping-bottles the following solutions:—

1.—Pyrogallic acid	60 grains
Alcohol	1 ounce
2.—Fresh carbonate of ammonia	60 grains
Water	1 ounce
3.—Bromide of potassium	12 grains
Water	1 ounce

Instead of directing to develop by the ordinary alkaline method, &c., I will now describe minutely, for the benefit of those who may not be familiar with alkaline development—for this is the all-important point to make either success or failure of the result—the method I have found most successful with these plates. I now refer to the making of a positive suited to the reproducing of the negative. To one ounce of water, temperature not below 70° F., add twenty-five to thirty drops No. 1 and one drop No. 2. Mi_x

* *Practical Photographer Almanac.*

with strip of glass; take the exposed plate from the water, rinse under tap, flow over the pyro solution, and keep in motion on the plate, and if rightly exposed, a thin but fully detailed image will appear; keep on the solution till on looking on the plate the image appears fully brought out, the high lights slightly tinted; then to the developer add fifteen drops of No. 3; flow over and return to the cup; next add to it fifteen drops No. 2, and again apply to the plate until you see the image by transmitted light vigorous and intense, without, however, carrying it too far. Wash, and fix in either weak cyanide or hypo solution; carefully wash, and place in rack to dry. An under-exposed plate yields a dark, olive-tinted positive; a correct-exposed, a rich, warm, sepia brown; one over-exposed, a thin, flat, reddish brown. To reproduce the negative, repeat the operation of exposure and development, using the positive in place of the negative. In cases where increased vigour is desirable in the negative, modify the developer as follows: Water, one ounce; No. 1, twenty-five drops; No. 2, fifteen drops; No. 3, ten drops; flow over the moistened plate till developed. If more intensity is required, add ten drops more of No. 2 and No. 3, or, after the first development, wash and re-develop with acid pyro and silver; wash, and fix. When a negative is desired different in size to the original, it can be reproduced by transmitted light in the camera, using the ordinary wet collodion chemicals, taking care to give sufficient exposure, and a rather weak developer. In my own practice, I have adopted this method in preference to either the dusting-on process or carbon positive.

GUP.

THREE were some quaint old verses which I was set when at school to transmute into Latin lyrics, and which were composed of a series of happy exemplifications of the idea that constant repetition means ultimate success. "The sturdy rock for all its strength" is bored through and through by tiny drops of water, and so on, with, of course, an appropriate moral about the ultimate success of unwearied constancy in love affairs. Although doubtless in a less exalted and exalting sense, the same maxim obtains in respect to innovations in photography. Take gelatine as an instance. Several years ago I went into Mr. Kennett's to buy my first sample dozen of plates prepared by his process. I remember asking Mr. Kennett's assistant at the time, "Now do you really think that gelatine will ever supersede collodion?" and the answer was, "Indeed, I do." I own that I was sceptical; nay, more, that I was inclined to scoff secretly at what I thought was the mere outcome of a temporary mania. And now, by dint of unwearied research and constant application, gelatine-bromide has soared to a pride of place in gazing up at which my scepticism has been converted into great, though not unlimited confidence; my scoffing into considerable, though not reverential respect.

After the above preamble I might be fairly expected to evolve, by way of an excuse, a series of valuable and novel hints as to the practical working of the gelatine processes. I am afraid, however, that it is but another case of the mountain bringing forth a mouse. My lamp is of no new form, and I think Mr. Jarman would laugh at the marmalade pot (oh, bother the pun!) which plays a not unimportant part amongst my gelatine paraphernalia. Stay, perhaps some of you gelatine workers might—and in gelatine most things are wildly possible—discover some use in that unprepossessing vessel, the stone ginger-beer bottle. It has struck me that this ought to be even handier than the ink bottle suggested by another contributor.

Don't all speak at once, and should any recognition of this grand addition to photographic—ahem!—apparatus be deemed desirable, permit me to remind you that "Kaleidoscope," care of the Editor, P.N., would like by way of a commencement to have those nineteen half-sovereigns he

asked for the other day in behalf of the Photographers' Benevolent Association.

M. Vidal "slung an ugly left." I wonder, by the way, whether M. Vidal, good English scholar as he is, can turn this slang into idiomatic French at MM. Cros and Ducos du Hauron last week, *in re* the photo-chromie controversy. He also came down rather "stark" (that is good old English, *not* slang) upon his fellow-countrymen about their apathy in respect to the real interests of photography. Of course, such a charge would fall as dead as possible if even insinuated against English photographers. Oh, dear, yes! Do we not take in the PHOTOGRAPHIC NEWS, and perhaps belong to a photographic society, and isn't this equivalent to advancing photographic interests? Oh, yes, of course it is! But, I say, can you tell me your candid opinion, from a pecuniary point of view, putting aside all thought of art and such-like twaddle, whether it is worth my while to throw up wet collodion, and take up something new? Shan't I be advancing photographic interests if I do this? Oh yes, of course!

If only all photographers were to read, mark, learn, and inwardly digest all the good advice that is showered upon them so liberally from every side, what a science photography would be in a few years! And if only some of them would read what Macaulay says about *cant*. Not long ago I heard a country photographer canting away about the "vibration of light," serenely indifferent to the fact that these three words comprised his whole knowledge of that subject. The same ingenious individual informed me, with a look of conscious pride, that he was in the habit of using his toning bath *hot*. He merely dips in the print, and in a few seconds the trick is done. I looked at some of his finished prints, and believed him implicitly.

Ah, me! the woes of an amateur photographer! Oh! Mr. Kaleidoscope, do come and photograph us in our lawn tennis costumes. And Mr. Kaleidoscope comes, and spoils a lot of whole-plates, because Ethel will persist in giggling, and Maud declares that to hold a lawn-tennis bat without waggling it round and round, and finally dropping it on Florence's fragile foot, is quite impossible; and when at last the picture is secured—oh! the delight of receiving a succession of diminutive missives, enquiring petulantly as to when the prints will be ready, and "Mayn't I have! just one directly, to show to someone?" and so on. Oh brethren amateurs, follow my advice, and never print anything but proofs from your negatives. Give them to a professional printer at any cost, and talk of him just as Mr. Spenslow talked of Mr. Jorkings in *David Copperfield*.

Many thanks, Mr. Henderson, for your developer, and may you soon be successful in removing the slight uncertainty attached to its use, which seems to be its only defect. I am anxious, too, to hear Mr. Warnerke's formula for a durable developer, which he promises to make public at an early meeting of one of the Societies. What about Mr. Werge's method of keeping the ferrous oxalate developer? Here is a splendid field for advancing photographic interest, and one which will not, I imagine, be abandoned the moment it is entered upon.

I fear my readers will consider this a very bald instalment of "Gup." But it is their fault, not mine. If they will do more, I will gossip more, and I am sure the pleasure of being patted on the back in print, as well as the sweet self-consciousness that they are bettering photography and "Gup" at the same time, ought to be the best of all stimulants to, at any rate, the well-wishers (may their shadow never grow less) of

KALEIDOSCOPE.

THE NEXT PHOTOGRAPHIC EXHIBITION.

FULL details of the arrangements for the Autumn Exhibition of photographs under the auspices of the Photographic Society of Great Britain are now accessible. The Exhibition, it appears, will be inaugurated by a *conversazione* on the evening of Saturday, October 4th, and will remain open daily—Sundays excepted, of course—until Thursday, November 13th. On Monday and Saturday evenings it will be open at half-price, thus affording all classes of assistants an opportunity of seeing the display.

The general restrictions as to the hanging of Oxford and inconvenient frames will prevail, and, indeed, the Hanging Committee will have the power of rejecting anything they regard as objectionable or undesirable. Whilst neat labels of subject, name, and address are permitted, anything approximating to advertising display will be rejected. Members of the Society will, as usual, be permitted to exhibit without charge; but non-members will be required to make a small payment toward the expenses of hanging their pictures. Until last year this Society had, with unexampled liberality, allowed all photographers not only to exhibit without charge or paying any share of the expenses of the Exhibition, but to compete for the prizes offered by the Society without paying entrance money. This was, so far as the Exhibition was concerned, obviously placing the members of the Society at a disadvantage, as they, by their annual subscriptions, helped to provide the prizes, and to pay the expenses contingent upon holding the Exhibition. Having had these points brought under their special attention, the Council last year resolved to make a small charge for space to non-members. A few protests were heard to the effect that such a course was "small," "illiberal," and "undignified." To all this the simple reply that it was fair and just is sufficient answer; and the same will prevail this year. That simple justice is aimed at may be seen by the liberal arrangements by which the charging plan is surrounded. In order that foreign photographers may not be deterred by such a condition, they are freed from its operations by the rule which, for the purposes of the Exhibition, regards foreign photographers as honorary members. Furthermore, it is arranged that should any of the exhibitors become members at the commencement of next session, the charges for space in the Exhibition will be remitted.

A new condition of some importance we are glad to see amongst the arrangements. It is to the effect that certain kinds of coloured photographs will be admitted. In the earlier exhibitions all photographs, whether plain or coloured, touched or unsophisticated, were admitted without distinction. Gradually grew a tendency to occupy a large amount of space with pictures which might probably have

had a photographic basis, a basis which was, however, entirely hid by a paint, so that the pictures were to all intents and purposes paintings by more or less—very often less!—skilled artists, and entirely devoid of photographic interest. To meet this manifest misuse of the Exhibition, the Council eventually resolved to exclude all coloured work from the Exhibition, confining it to that which was essentially photographic. This, of course, did not necessarily imply any disregard of the work of the artist in combination with photography, as some seemed to fancy when the edict went forth. It was simply a means of excluding trade displays of coloured work of no photographic interest, and very often without any artistic merit whatever. The new condition is as rigid as the old one in regard to such work. All photographs coloured by hand will still be excluded. But photographs coloured by scientific or mechanical means will be admitted. The last sentence as it stands may seem open to challenge. The carping critic may exclaim: "What! exclude pictures coloured by the hand of an artist, and refuse the thousands who visit the Exhibition the opportunity of seeing the perfect accord of photography and true art, and admit the work of indiscriminating mechanism? Despite, however, the apparent anomaly, the condition is a wise one. Photography is partly a scientific and partly a mechanical means of producing and multiplying pictorial designs, and methods of colouring which are analogous in their character may fitly be exhibited in the same gallery. Of late years, various scientific and mechanical methods of adding colour to photographs have been devised, and are worth encouraging, as essentially promoting photographic progress and prosperity. We think, therefore, the idea of opening the Exhibition to ingenuity in this direction is a happy one, and one of which we hope to see advantage taken in the forthcoming Exhibition.

Medals, as we have before announced, will again be offered for competition, the widest possible discretion being left in the hands of the Judges, who are to reward any form of scientific or artistic excellence which may be discovered in the contributions. The Judges are beyond challenge admirably well suited for the office. Mr. Marks, the well-known Royal Academician is one. Mr. Marks is, we believe, not only a painter of rare distinction, but a gentleman very familiar with photography. Mr. Oules, Associate of the Academy, is recognized as one of the very ablest portraitists of the day. The two members of the Council are Mr. Valentine Blanchard and Mr. John Spiller; the two non-official members of the Society are Mr. T. M. Brownrigg and Mr. G. Shadbolt; whilst the President is, of course, a member. These gentlemen will form a jury which we venture to believe will command the suffrages of every member of the Society.

MAGIC LANTERN NEWS.

THE magic lantern is very popular in America. A journal devoted to its interests, entitled the *Exhibitor*, is published in Philadelphia monthly. From this journal we make a few extracts which will interest some of our readers. Speaking of the magic lantern in Germany, we are told that Professor Bötcher, of Berlin, Germany, is probably the greatest lantern exhibitor in Europe. For six months in each year, beginning in October, he exhibits in the Royal Tragedy Theatre, enjoying the patronage of the Court. The lanterns are concealed behind the screen (of about 16 square feet), which medium is prepared in a solution that renders it very transparent, and causes it to hold the projections with remarkable clearness. The entertainment is announced as an Instructive Soirée, and is in three parts: 1. *Travel*, in which some one country is beautifully illustrated. 2. *Science*, in introducing the sun, or moon, or microscopic projections. 3. *Variety*, in which paintings, statuary, dissolving views, &c., are finely presented. The Professor's pictures are elaborately

painted in oil colours, frequently costing from \$50 to \$125 each, and never being valued at less than \$25. This magnificent collection of paintings and the instruments used for projecting them are worth about \$40,000, and their use nets the Professor about \$7,000 per annum, clear of all expenses.

Professor Bötcher spends his six months of intermission in the preparation of new slides, to add to his already enormous collection; and these new scenes must be of the highest excellence in order to please the critical people of Berlin, who have learned to expect great things at the Instructive Soirées of the Dramatic Theatre Royal.

The use of the lantern at a masked ball is a novelty which was recently tried in Philadelphia. We are told that the "Canstatter Volksfest Verein gave their annual masked ball at the Academy of Music, in this city, on February 19th. The attendance numbered about 4,000, and many novel features were successfully introduced. The vast parquet and stage were floored over, as usual on such occasions. At 8.30 p.m., a man attired as a magician advanced upon the platform, accompanied by a troupe of gymnasts attired as harlequins. The lights of the immense chandelier were turned out, the wall lights turned down, and a large screen hung before the curtain; and on this screen a long and varied series of crayon caricatures, comic slip-slides, ludicrous movable figures, and laughable scenes were projected in rapid succession by the magician, who very skilfully manipulated a pair of oxy-hydrogen exhibitors' lanterns. The harlequins imitated the various scenes in sounds and actions; the imposing magician displayed great dexterity, the audience laughed and applauded, and all went merrily until 9 o'clock, when all lights were turned on, and with music, tableaux, singing, and a grand march, the carnival of fun pursued its jolly way."

An article in *Frank Leslie's Illustrated Newspaper* describes the application of the lantern in singing lessons. Copies of the music, having been made by photography in the shape of slides, are thrown on the screen, so that hundreds may read the same score. Here is what *Frank Leslie* says: "Every Sunday-school teacher is fully alive to the ease of gathering children into classes as the holidays approach, and the difficulty of retaining them after the annual distribution of presents. Provisions have to be made constantly for attractions to draw the children to the school-rooms, and these in the course of a few months greatly tax the ingenuity and tact of the teachers. Pic-nics, excursions, and May-day frolics in warm weather; tableaux, stereopticon exhibitions, illustrated lectures, and concerts in the winter, follow one another as interest in the curriculum begins to lag; and still new devices have to be contrived when these features have lost their attractions. And in many instances entertainments arranged solely for the little folks prove so absorbing and agreeable to the children of a larger growth, that they pass from the Sunday-school room into the church itself. This fact is illustrated in a novel manner in Boston, where the throwing of verse after verse of a hymn upon a screen by a magic lantern, first adopted as a new idea in school entertainments, has led to the laying aside, temporarily, at least, of the hymn-book during the congregational singing in a number of churches. Where this innovation is made, there is no reason why one who can sing won't sing. The objections of having no book, or having left the book at home, or of eye-trying fine type, are annihilated. The apparatus requires but a small amount of space, and necessitates no disfigurement of auditorium or walls. It has already been found to please the old as well as the young, and there is no reason why the plan should not be widely adopted, particularly during the camp-meeting season."

A novel use of the lantern has been made on the Pennsylvania railway, where it has been made useful for drilling trains.

"At all railroad depots and junctions there are locomotives whose sole duty is the drilling of trains. This consists in running empty cars to and from sidings, breaking ariving trains into sections, and connecting these sections with de-

parting trains. Of course, this is being done all night as well as all day, and especially demands correctness and dispatch. In a prominent position is located the telegraph office, where the coming of trains and the distribution of the cars is announced by train officials from other stations; and these announcements must be conveyed to the engineers of drilling engines, who are always in waiting, and at some points almost constantly employed.

"They may be readily signalled by day, but until recently there has been difficulty in conveying the information with certainty and expedition by night. A number of experiments were tried on the Pennsylvania railroad at Harrisburg recently, with lanterns using various lights, and the following method was finally adopted as giving unexpected satisfaction. A piece of ground plate glass, 22 by 30 inches, was set in a commanding position, and on it was quickly painted in jet black letters the just received despatch:

Train 106—Due 12.05.

First 3 cars—Philadelphia.

Second 3 cars—Pittsburg.

Last 2 cars—Erie.

"An exhibitor's lantern was set up about six feet behind the plate glass, all of its lenses being removed except one of the condensing, which was placed with convex side outermost, so as to form what is called a lens box. The best double-wick coal oil lamp was used, and the message became clearly legible to the engineers 120 feet distant. The tanks for oil are made of extra large size; and two complete lamps, trimmed and filled, are sufficient for use throughout the night. The plate glass is readily cleaned off after the arrived train has been drilled, and another message lettered on it."

In relation to illuminating oils, we learn that the candle power of house gas is only 16 to 17, and that of the old lard oil lamp about 20; but the best double-wick coal oil lamps give from 34 to 40. Camphor dissolved in oil certainly whitens the flame, but the gum collects upon and hardens the wicks, so that it is but seldom used, except in trial exhibitions.

PHOTOGRAPHY AND THE DUTCH ARCTIC EXPEDITION.

BY W. J. A. GRANT.

In attempting to write a photographic account of the cruise of the Dutch schooner *Willem Barents* to the Polar seas in the summer of 1878, I fear I have but little of interest to relate regarding photography, owing to the fact that the opportunities for going ashore were few and far between; and when we were able to land and work on shore, the weather was often so bad that photography of any sort was almost hopeless. However, we got between fifty and sixty negatives, including views in the north-west of Spitzbergen, Novaia Zembla, Bear Island, and in the ice between Spitzbergen and Novaia Zembla.

The ship *Willem Barents* is small, but admirably fitted for ice navigation, being extremely strongly built, and having every requisite for such a voyage as she was intended for. We had every appliance for deep sea sounding, for taking deep sea temperatures, and for dredging, and a large quantity of magnectical instruments under the care of Lieutenant Speelman.

We left the shores of Holland on May 6th, touched at Bergen, in Norway, a week later, where we remained a few days for some slight repairs, and then at once turned the ship's head towards Jan Mezen Island, and after a tedious voyage, with head winds and gales, sighted that island on June 8th. It happened to be a very fine, clear day, a thing that seldom is met with just at this part of the Arctic Ocean, and we actually saw the island—or, rather, the huge mountain—Beerenberg 112 English miles off. The island itself is long and narrow, rugged, with high-peaked hills, and at the north-east end rises the Beerenberg, nearly 7,000 feet high, almost straight out of the

sea. This was really a grand sight, and well worth seeing. The mountain was one mass of snow nearly to the water's edge, and the contrast between it and the dull grey-coloured sky and dark blue water caused a magnificent effect. We were, unfortunately, quite unable to land, owing to a strong gale having sprung up, and we reluctantly had to leave the island, as we could spare no time to wait for better weather. On June 17th we reached the main pack on the east coast of Greenland, and on the 18th were in sight of the north-west coast of Spitzbergen, having coasted along the edge of the ice all the way. The west coast of Spitzbergen is very beautiful when seen from off shore. Huge glaciers are seen pouring their volumes of ice through the valleys into the sea, and the blue-peaked hills, most of which are snow-capped, add much to the general grandeur of the scene.

On the 19th we anchored between two small islands on the north-west coast, called in the charts the Outer and Inner Norways, and near Cloven Cliff, a well-known landmark in these parts. In the old Dutch whaling days the "Outer Norway" was called *Leeuwsehe Mitkyk*, "or Zeelander's Lookout," so named from the fact that it was from here the whalers of Holland used to watch the movements of the ice while anchored close by. At this place began my photography, and I must say the first results were not encouraging. Perhaps here it may be as well to say a little about my apparatus, &c., and the dark-room. On board a small ship it is hard to find any place where one can develop dry plates and work with wet, and I was lucky in getting what I did, namely, a little place right in the peak of the ship, in front of the men's quarters. As far as darkness went, I was all right; but the great drawback was the damp and a leakage in the deck above, and it was often with great difficulty that I could prevent salt water dropping into the bath, and many a plate have I had destroyed by water dropping on it while taking it from the bath or slide. The damp was so great that I left a negative to dry there once as an experiment, and at the end of three months it was no drier than when put there. A dark slide, left there for a few hours only, refused to open at all, and the whole place was so charged with moisture that, do what I would, at the best the work was not easy.

The great difficulty in getting satisfactory results is caused by the great amount of mist in these latitudes. You may get many fine days here and there about Spitzbergen, and in the Greenland Seas, Ballin's Bay, &c.; but in the sea between Spitzbergen and Novaia Zembla, and on the coast of Novaia Zembla, a day even fairly free from mist is very rare, so that one might be anchored for a week at any spot, and hardly be able to see anything all the time. This is often very provoking; but I must say I was often very lucky, just being able to expose a plate or two before the mist became really thick. Once in Novaia Zembla I remember having to remain by my camera three hours before I could expose, every moment expecting the mist to rise for a few minutes; and once I remained by it for more than four hours, and after that had to return to the ship unsuccessful. I had one fine day in *Matotshkin Scharr* in Novaia Zembla, and one fine day—or portion of one—at the north-west point of Novaia Zembla; one fine afternoon at *Leeuwsehe Mitkyk*, and a fine day and afternoon at *Amsterdam Island*. With these exceptions the weather was always bad when I was photographing—mist, sleet, and a little rain, with dull gloomy-looking clouds for ever hanging over the hills, and causing a view, however fine in reality, to look heavy and desolate. I can fancy some magnificent photographs might be made in the north, if only one was able to remain long enough at one spot to make sure of getting a favourable day; but this is of course impossible in the case of an expedition ship, and often one has to rush ashore and back again without having time to choose one's view, or go the shortest distance inland. Of northern scenery,

Spitzbergen and the best coast of Greenland are, I think, much finer than Novaia Zembla, and I should never recommend any one to attempt to go to that miserable land for artistic purposes.

I worked the wet process when possible—*e.g.*, when anchored near shore, or when amongst the ice—but most of the work was done with Liverpool collodio-bromide dry plates. I do not suppose I brought back a dozen wet plate negatives altogether. By using care, there is no difficulty in working these plates in the North, and as for the cold, I have not had much experience with it, because we never had it more than a few degrees below freezing point.

I found much difficulty in obtaining water fit to wash the plates, for there was nearly always some silt in the water used on board, and there was so much iron rust in it that it generally took some four or five hours to thoroughly clarify and filter enough for three or four plates.

My size was $8\frac{1}{2}$ by $6\frac{1}{2}$, ordinary bellows-body portable camera, with the wide-angle view lenses and rectilinear of Dallmeyer. Great care was taken with the double backs, which were always kept in an air-tight tin-case; without this precaution, the damp will invariably destroy them. For wet plates, everything as usual, only I found an old developer, several weeks old, work better, and even quicker, than one a day or two or a week old. Of this I had no doubt, as I made many experiments with both old and new. A candle shaded with non-aetinic silk was the light, and when in harbour my "dark-room" was, except for the damp, by no means a bad place to work in. At sea it was terrible, and very hard to work in, for, right forward as it was, the motion was very great, and it required more skill than I had to develop dry plates and prepare wet again. When working among the ice, one was repeatedly knocked off one's legs, while in the midst of developing, by the ship's frequent charges and collisions while forcing her way through the floes.

When we arrived at the N. coast of Spitzbergen there was very much snow on the ground, which made the walking very hard when carrying apparatus. Sometimes it was hard to get on at all, and once I was nearly two hours getting over some 300 yards.

The snow was mostly deep and soft; one might get on a few steps, and then down one would go up to one's neck, and perhaps come on the top of some sharp pointed rock; at other times, one has to plunge and toil along with the snow a good deal over the knees; at other times, one has to scramble over large loose pointed rocks; and at others, up hills which seem hopeless to climb, as all the rocks and stones are loose, and rattle down with you at every step. Now and then, hard crisp snow was met with, and then the walking was very easy.

We remained at *Leeuwsehe Mitkyk* until the 23rd, which day was really fine; all the rest were miserable. We then steered eastwards in order to take soundings and serial observations near the pack; but on the 24th a heavy gale sprang up, and we had to lay to, and soon bore up for *Amsterdam Island*, a little to the south of our former anchorage, but the weather clearing we again made for the pack, though on nearing it found the sea too high to attempt to enter it, and so had again to turn away.

Being by this time near *Welcome Point* on the north coast of Spitzbergen, and as the sea was calm, some of us made an expedition towards the shore, which seemed about five miles off. I took my apparatus, hoping to get some good views, but we found the shore at least twelve miles off in reality, and were unable to get within two or three miles of it, owing to the ice; so we simply had to cook our dinner on the ice and return to the ship, having been absent all the day, my photographs consisting simply of groups on the ice, there being nothing more to do, and it not being

possible to photograph the coast, as the ice on which we were was in motion.

It would be tedious to your readers if I were to describe all the details of our working amidst the ice, &c., so I will simply say we arrived at Amsterdam Island on the 27th, and anchored in a fog, some two hundred yards from shore. We remained here until July 1st, and with the exception of one fine day the weather was miserable—snow, mist, and much wind, rendering photography almost hopeless. We found here an old Dutch burial place, and on many of the coffins inscriptions could still be made out, with various dates from 1635 to 1720. Two hundred years ago the Dutch used this island as their head-quarters during the whale fishing seasons, and the large number of rude graves show that many left their bones on this desolate shore. It was very interesting to see this place, and some of the bodies still had clothes on, and in some cases the hair of the men was on their heads, as though they had been but recently buried.

At midnight, just before we left the place, we all went on shore to the burial ground, where we had erected a memorial stone to these brave old mariners, and before leaving, the captain made a short speech to the men, who were all photographed in a group. The light was very bad, and a mist came on, so that nothing very splendid was the result.

Next day (July 2nd) we anchored further south—in Robbe Bay—to take in water, and while here we had too much mist to do anything in the way of photography; and in the evening of the same day we made for the westward, and on July 4th reached the Pack, and took soundings and deep sea temperatures in 1,360 fathoms. After this, we steered south, and on the 13th we reached Bear Island after much fog and general bad weather. Here we found some letters left for us by the Norwegian scientific steamer *Voringen*; and after remaining here for a few hours we made direct for Vardo, in the north of Norway, to post letters, &c.

Bear Island is a melancholy looking place, with one mountain called Mount Misery; all the rest of the island is bare and ugly in the extreme. I was only able to get two negatives here, owing to the mist.

After making a line of soundings and temperatures to Vardo (which place we reached on July 22nd), we steered north again, and by August 3rd were well in the ice in lat. $77^{\circ} 51'$ and long. 45° E., and were unable to get further north. For ten days we were among the ice, and here I got a few negatives. On August 8th we had nearly reached 35° long., being in lat. $77^{\circ} 44'$, and here we were very nearly beset for good. From aloft, nothing could be seen but ice in all directions, and for some time our position seemed hopeless; but a northerly gale, which eased off the ice at the edge, came to our assistance, and by the 10th we were quite free again. We had run out through nearly 70 miles of loose heavy ice, and many a hard bump did the ship get during the time. We now steered for Matotschkin Scharr, in Novaia Zembla, sounding, dredging, &c., all the way, and after rather a slow passage, anchored there on August 21st.

Here we remained five days, and nearly all the time I was photographing during the day and developing through the night. With one day's exception, the weather was misty and bad.

We then coasted up the west side of Novaia Zembla, and were some days off Capes Nassau and Troost on the N.W. coast, where we landed and made observations, &c. The weather was so bad here, and the season getting so late, that we had to leave these latitudes; and after once more going north and meeting ice in lat. $78^{\circ} 17'$ N. and long. 55° E., we made our way back to Norway, reaching Hammerfest September 26th, all on board being glad to get out of this sea of mists and fogs. We arrived in Holland in the middle of the following month, after a very successful cruise as far as the general scientific work was

concerned, though my special branch was not quite all that could be desired. On such an expedition there are so few opportunities for landing that it is quite impossible to make a large number of photographs; and the weather is generally so bad, that even when one can land the chances are much against anything being done. I was more fortunate than I might have been with the weather, and, by continual watching day and night, generally managed to get something each day on shore.

As I write, I am once more on the *Willem Barents*, and this time I fear the chances will be still fewer than during last cruise, for we have so much sounding and dredging to do in the Barents Sea, and, if possible, in the Kara Sea, on the east side of Novaia Zembla. We hope this year to reach Barent's Ice Haven on the N.E. coast, and there erect a memorial stone to one of the grandest pioneers of Arctic exploration.

Much work we hope to do in taking serials of dredging and magnetical observations, and if the Dutch go on as they have begun, they will probably, ere long, once more take the lead in Polar exploration, and add vast knowledge to general scientific research.

Vardo, Norway, June 12th.

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE following are the arrangements for the next Exhibition of the Society, which will be held at the Gallery of the Society of Painters in Water Colours, 5A, Pall Mall East, London, S.W. It will be inaugurated by a *conversazione*, open to members and their friends, at 8 p.m., on Saturday evening, the 4th of October. The Exhibition will remain open daily (Sundays excepted), from Monday, the 6th of October, until Thursday, the 13th of November. Admission (from 10 a.m. till dusk), one shilling. It will also be open every Monday and Saturday evening. Admission (from 7 to 10 p.m.), sixpence. Members will be supplied with tickets to admit their friends.

All packing cases must be sent (carriage paid), addressed to the Photographic Society of Great Britain, care of Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital, London, so as to arrive not later than Friday, September 26th.

Pictures by hand will be received at the Gallery, 5A, Pall Mall East, on Friday, September 26th.

No packing cases can be received at the Gallery.

Each exhibitor must send a letter of advice (containing a description of each picture, as also a statement of process, and any further detail, to be inserted in the catalogue), addressed to the Hon. Secretary, Photographic Society of Great Britain, 5A, Pall Mall East, London, S.W.

Each frame or picture may have the exhibitor's name and subject neatly inscribed, but no address, or anything in the shape of an advertisement, will be permitted.

No pictures in Oxford frames, or any previously exhibited in London, will be admitted.

Photographs coloured by scientific or mechanical means will be admissible. Photographs coloured by hand will be excluded.

The hanging committee will have the power of rejecting any pictures forwarded.

Medals will be placed at the disposal of the judges, for artistic or scientific excellence.

The judges will consist of the following gentlemen:—

Two Artists (Painters), H. Stacey Marks, R.A., W. W. Oules, A.R.A.; the President of the Society, James Glaisher, F.R.S., &c.; two members of the Council, Valentine Blanchard, John Spiller, F.C.S.; two members of the Society, T. M. Brownrigg, G. Suadbolt.

The Exhibition will be open to all photographers; but to non-members a charge of one shilling per square foot will be made for wall space; the minimum charge being five shillings. Foreign photographers will, for the occasion, be

considered honorary members. The charge for wall space to those exhibitors who may become members of the Society at the November meeting will be remitted.

L. DARWIN, Lieut. R.E., Hon. Sec.,
Brompton Barracks, Chatham, Jul, 1879.

SOME HISTORICAL RECOLLECTIONS OF PHOTOGRAPHY.

BY F. S. BEATTY.

"We are aware of Mr. Beatty's long connection with photography, and of his labours in connection with permanent printing which we have the pleasure at all times recognizing.—PHOTOGRAPHIC NEWS, September 16th, 1864."

My long connection with photography, a connection now entering upon its fortieth year, induces me to give a brief statement showing how far I have been instrumental in the infancy of photography of fostering and promoting its interest, which may be interesting and useful to those who admire and follow the art as a profession.

About this time, 1839, the scientific journals of all countries made the announcement that M. Daguerre, of Paris, had discovered a means by which the fleeting images of external objects depicted on the ground glass of the camera-obscura could be retained on a tablet of polished plated silver plate, and be permanently fixed thereon. Splendid specimens were exhibited in Paris of its architectural buildings, bridges, &c. The most distinguished and scientific men of that day were taken by surprise by the publication of so wonderful an invention, and intense anxiety was experienced by all awaiting the publication of the details. Although communicated to the Academy of Sciences the 7th January, 1839, the process was not published until the 15th June by M. Arago to the French Chamber of Deputies on the occasion of the French Government awarding to M. Daguerre, in conjunction with M. Isidore Niepce, each a pension for the discovery and publication of all details.

Ever watchful then, as well as now, to investigate into any new discovery that may be useful and beneficial to the advance of science or art, I resolved at once to exercise what ability I possessed to accomplish what M. Daguerre had discovered, and proceeded to work at the problem, being at the time an amateur optician, chemist, and careful manipulator (my profession being an engraver). After many failures and up-hill work, I was much surprised when I succeeded in my object to my entire satisfaction, as a letter of mine dated 20th September, 1839, published in the *Belfast News Letter* of that date will more fully show, which is annexed:—

From *Belfast News Letter* of September 20th, 1839.

THE DAGUERRETYPE.—On this curious subject, the following interesting letter has been addressed to us by Mr. Beatty, the well-known engraver of this town. We have also received the specimen to which he refers, and the effect noticed by him is extremely singular.

To the Editor of the *News Letter*.

SIR,—Being occasionally engaged since the announcement of M. Daguerre's extraordinary invention of fixing on silver, plated on copper, the minute images of external objects, produced by means of the camera-obscura, after a number of experiments, I was somewhat surprised to find, that in using silver paper, the effect was different from silver plated on copper, although treated in a similar manner. Silver plated on copper gives the true effect of light and shade—while silver on paper gives the opposite—namely, the light parts of the subject are dull, and the dark shades are, in a proportionate degree, light. In order to convince you of the fact I send you a specimen; but our days of late having been cloudy, you cannot expect it to be as perfect as I would wish. I hope before your next publication to be able to submit to you a specimen upon silver plated on copper, and silver on paper, in order that you may more completely understand the difference. Hoping that this communication may have the effect of promoting inquiry on the subject, I remain, your obedient servant,

FRANCIS S. BEATTY."

It is only now after the lapse of nearly forty years, in which I have had experience of many vicissitudes of fortune intermingled with pleasure for the love of our beautiful art, and which entailed upon me an less expense of time and money in endeavouring to promote its interests, and at a time when there could be no reasonable prospect of a return for the outlay. However, I can never divest myself of the pride I possess in having taken an active part in the infancy of this invention, and by my humble abilities aiding to bring it forward to its present state of perfection. I question whether there is any record of the successful accomplishment of a Daguerreotype picture in Great Britain at so early a date, September 20th, 1839, nearly three months after its first publication of June 15th, 1839.

In the PHOTOGRAPHIC NEWS of November 29, 1878, there appears a critical notice of a work (Scientific Memoirs, by John William Draper, M.D., L.L.D.), which, to me, is very interesting. I therefore take the liberty of quoting a paragraph. "In the early days of photography a galaxy of the most distinguished philosophers of the day were fascinated with the field for investigation and discovery which it opened out to them, and they devoted themselves to aiding in establishing the new art. Treasures of time, thought, learning, and experiment, were lavished on it by the most capable chemists and physicists of the period." Probably the only survivor of those who have prosecuted their researches with unabated ardour is Dr. Draper.

All I assume to be is that of an humble individual of a practical turn of mind not trained to scientific investigation. My authorship extending only to such matters as can be conveyed in a letter on a scientific subject in a periodical, and without wishing in the least to detract from others their merits of discovery, or their practical application of it into practical results. I think, from the facts I have already stated in this communication, that photographers will concede to me as proved that I had the good fortune of recording myself in the field earlier than any other person.

It was in March, 1840, that the first photographic portrait from life was effected by Dr. Draper as recorded in the *Philosophical Magazine*, and consequently nine months from the date of the publication of M. Daguerre's discovery.

In the latter part of 1839, and continued in 1840, Belfast, my native place, its architectural buildings, old long bridge, spanning the river Logan, was delineated by the Daguerreotype, executed by me, and were much admired by the nobility and gentry of the town and neighbourhood, and noted in the most flattering terms by the local newspapers of that day.

In June, 1840, Mr. Richard Beard patented in Great Britain the concave silvered mirror for the production of Daguerreotype portraits, being a communication from Mr. Woolcot, an American photographer; and being desirous of giving this method a trial, I immediately set to work to grind and polish a concave mirror of short focus in speculum metal, having previously ground and polished them for reflecting telescopes.

After considerable delay I accomplished my object, and in 1841 was enabled to produce portraits. Having communicated my success to Mr. Beard, he invited me over to London, and in the October of that year found me in the Polytechnic Institution, when I was introduced to Messrs. Cooper and Goddard. At this time Mr. Beard was establishing a similar institution in Southampton; he, therefore, desired me to take my part as an operator until he would come home. In the meantime he would examine my specimens, which he took with him.

So great was the excitement created in London amongst the nobility, gentry, and moneyed classes at this new species of portraiture which was then being produced at the Polytechnic, that during my stay the average amount of money taken each day amounted to, I was told, £150. However,

this included expensive cases, frames, and jewellery. In the waiting rooms of this establishment you would see waiting their turn to enter the blue glass-roofed operating rooms, the noble dames and daughters of England's aristocracy, accomodating each other as well as their limited space would allow, awaiting for hours together before their desires were accomplished. I venture to say that if our present race of photographers were to present to the dom sties of any of our aristocracy portraits such as were supplied to the Polytechnic of that day, they would not accept them, so beautiful and cheap as they are now produced, showing the onward march of improvement.

On the arrival of Mr. Beard from Southampton, he mentioned to me his intention of establishing a Daguerreotype portrait gallery in Dublin, and that if I would accept of the operative management he would pay me a per centage on the work done. Having been in pretty good circumstances at the time, his terms did not meet my approval, and I therefore declined the offer.

The Parabolic glass mirror soon gave place to the original camera in consequence of the use of more sensitive chemicals being employed to sensitize the Daguerreotype plate in addition to simple vapour of iodine, bromine and chlorine were used.

Opticians of note applied their abilities to make lenses for the camera of Daguerre. The most successful were Voightlander, of Vienna, and the late Alexander Ross, of London. Photography now got a start in the right direction, and exquisite portraits were the result, the patented mirror was abandoned, and the art became free to all.

The glare of the silver plate was got rid of by subjecting the finished picture to the action of the galvanic battery, by depositing upon it a film of gold, which not only preserved it from atmospheric injury, but gave to the picture a warm flesh-coloured tint which had a pleasing effect, while the splendid detail made portraiture of that day unqualified at the present.

Their multiplication by printing being impracticable, their value was considerably enhanced by their cost, therefore, limiting their productions as a profitable commercial transaction.

In 1842, in connection with another, we built a gallery for Daguerreotype portraiture in a central situation in Belfast, which was carried on for a considerable time. However, the expense of a Daguerreotype portrait being above the means of the general public, we had to abandon the undertaking.

"It is not so generally known among our citizens as native merit demands that it should be, that the first person who introduced this new and beautiful art of imitating nature into Great Britain was Mr. Francis S. Beatty, of Castle Street, a gentleman whose talents in several branches of the arts are as varied as they are creditable. We have seen both portraits and architectural views produced by Mr. Beatty, which, in our opinion, could not be surpassed, either for accuracy of copy (which, however, is inseparable from the art), or for the ill with which the most minute details had been "fixed." His skilful public patronage is supported by abilities of which his fellow-classmen ought to be proud, independently of the credit due to him for his successful prosecution of the photographic art."—*Banner of Ulster*, 1842.

Mr. Fox Talbot's Calotype pictures were executed by me, positives from paper negatives; some of them are now before me at that date; a Daguerreotypist would not admire them. Time went on, and progress was slow, until Mr. Archer's collodion process was made public; this gave a new impetus to the subject, to portraiture as well as landscape, cheapening the process, and placing before the public a beautiful glass positive for a trifle.

Photography became at once an established and fashionable business, and, of course, I once more joined the profession. Then came the carte-de-visite or Albion portrait, followed by the cabinet, and enlargements of all dimensions, &c.

To be continued.

Correspondence.

PHOTOGRAPHIC ARTISTS' SUPPLY ASSOCIATION.

Sta.—Your correspondent "Kaleidoscope" has made some mis-statements regarding the Photographic Artists' Co-operative Supply Association, Limited, which require correction.

Therefore let me state that the stores and offices of the P. A. C. S. A. are located in 43, Charterhouse Square, not at Goswell Road.

The P. A. C. S. A. neither pretend nor profess to be any other than ordinary traders, except so far as regards their working on the co-operative system. This system was adopted by reason of the heavy discounts (varying from 15 to 50 and 60 per cent.) which were offered to the promoters of the Association on the prices of most photographic goods previously to the opening of their stores, and also by reason of the co-operative system appearing to the minds of the promoters to be the one most fair to both buyer and seller.

This is the whole history of the little catalogue which has so excited "Kaleidoscope's" disdain. If you see anything in this which you consider unfair to competing traders, by all means let your correspondent point it out in your columns; otherwise "Kaleidoscope" will perhaps allow a strictly commercial concern to start untrammelled by prejudice, and to be judged of, like all the other photographic trading establishments, by the experience of the photographers who may be their customers, by whom alone they can be fairly judged.

Considering that "Kaleidoscope" candidly acknowledges that he does not know much about his subject, you will no doubt consider it but fair play to admit as many lines from one who can give yourself or your readers all information they may wish for.—I am, yours obediently.

H. KERR, Managing Director P. A. C. S. A. Ld.
43, Charterhouse Square, August 7th, 1879.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF IRELAND.—The monthly meeting of this Society will be held at the Queen's Institute on Wednesday next, the 13th August, at 8 p.m.

THE HAIL STORM.—The hail storm which occurred in the west of London on Sunday morning was singularly disastrous to glass houses. We have received from Messrs. G. Tholy and Co. a design of a studio they have recently devised, and as the photograph was taken the day after the storm it presents the appearance of a building which has sustained a siege. We shall have something to say on the studio hereafter.

LANTERN EXHIBITION AT THE ALEXANDRA PALACE.—A correspondent sends us an account of a Sunday school festival, held in the Alexandra Palace, of which an exhibition of photographs by dissolving view apparatus formed a portion. The screen, we are told, was "twenty-five feet square, or, as described in the programme, illuminating over six hundred feet of canvas. The title was 'Bauties of Nature and Gems of Art.' Every photograph came out to the edge of the sheet sharp, clear, and without colour, and fully bore out the title given. Some two hundred views were passed through in the short time allotted (one hour) under a very careful manipulation. Messrs. W. H. Oakley and Co. gave this entertainment under trying circumstances, as the sun's rays could not be blocked out in consequence of faulty window blinds in the theatre. The light must have been very powerful to have counterbalanced daylight as it did. Messrs. Oakley well deserved the hearty applause they received from the delighted audience."

THOMAS A'KEMPIS.—Mr. Stock's long-promised facsimile reproduction of the autograph manuscript of the "Imitation of Christ" will be ready for publication in the autumn. A curious chapter of accidents has delayed its earlier appearance. Firstly, the brightest days only afforded sufficient light for

photographing in the quadrangle of the Royal Library at Brussels; then several of the negatives were broken in transit, and others had to undergo a special process after being taken, because of the dim and discoloured state of the original manuscript. Then the animal size employed in making the first batch of Dutch paper putrefied in the hot weather of last summer. Then twenty-five of the electro blocks were destroyed by a fire at the printer's, the entire reproduction of which was necessary. Lastly, the second lot of Dutch paper was spoiled by too much wetting, causing the ink to run in printing, and a third lot of paper had to be made. The relation is curious, as it illustrates some of the difficulties in the way of facsimile reprints. From some sheets we have seen we are glad to say every difficulty has been surmounted, and that the beautifully regular Latin manuscript of the original has been reproduced with perfect clearness.—*Bookseller.*

THE COMEDIAN AND HIS PHOTOGRAPHS.—Mr. Charles Roberts, the well-known theatrical and music-hall agent, of York Road, Waterloo Road, was summoned at Southwark by Harry Lester, an American comedian, for detaining a number of photographs of himself and wife in different characters. The complainant said that he and his wife were well-known in the United States as characteristic comedians, and having made up his mind to visit England, he sent by a friend a number of photographs of himself and wife in their various characters to be delivered to his wife's mother at Islington, and at the same time a notice to defendant to look out for apartments for him. By some error, his manager left the photographs with defendant's clerk, who said he would show them to his master, and afterwards forward them to their destination. About a fortnight ago he and his wife arrived in London, and he proceeded to defendant's, and finding the photographs had not been delivered to his mother-in-law, he asked defendant to return them, as they were necessary to forward to managers in the country to seek engagements for himself and wife. Defendant denied all knowledge of them, and as it was important he should have them, he was compelled to take the present proceedings. Mr. Roberts said that thousands of photographs were sent to him by actors and others in search of employment, and it was impossible for him to know where they all go to. They were forwarded by him to managers all over the kingdom in the course of business. He had no knowledge of defendant's photographs, and had gone through all he had, and could not find one that could be identified as belonging to the complainant or his wife. Mr. Slade told complainant there was no proof that defendant had the photographs in his possession, therefore the summons must be dismissed. He could, however, proceed against Mr. Roberts in the County Court to recover damages for the loss of the photographs.

To Correspondents.

B. L. M.—The troubles you describe are not uncommon in hot weather, and can only be met by the use of extra care and precaution. Keep the operating room cool by occasionally sprinkling with water. A wet cloth wrapped round the bath will keep it cool. Keep cool and calm yourself. Let dust be removed from the operating room every evening, so that none is left to fly about the room in the morning. Avoid the use of very strong solutions. A 30-grain silver bath, and a 15-grain developer, will be found quite strong enough.

A. DUFFER.—We fear that you really deserve the name you have adopted. How could you imagine that in order to neutralize a negative bath you should continue adding carbonate of soda until effervescence ceased? You have thrown down all the silver in your bath as carbonate, which may be converted into nitrate by means of nitric acid. The idea that you must add the soda solution until there is no more effervescence is altogether an error, as there will be constant effervescence on adding it until all the silver is precipitated as a carbonate. The proper plan is very simple. Make a 10-grain solution of bicarbonate of soda and keep it for use. Add of this a few drops at a time, shaking the bottle containing the silver solution, and then allowing it to stand a few minutes. Continue the addition until there is, after standing, a slight permanent turbidity, which will show that all the free acid has been neutralized, and a trace of the nitrate has been converted into carbonate of silver. Now place the solution in the sun for a few hours—or, if possible, a few days—then filter, and try a plate. It is probable that the bath will work clean and bright at once; if not, add a slight trace of dilute nitric acid.

YOUNG HAND.—You will find your collodion improve after keeping a few days. Newly oxidized collodion rarely works so well as that which has been mixed a week or two. The early volumes of the *Photographic Journal* you have been reading are very useful and interesting, but very much experience in relation to collodion has been gained since that time, and different formulae are employed in its preparation. Whilst you may gain many useful hints from the volumes in question, you must not rely upon them absolutely for modern practice.

NORTH COUNTRY.—Personal attendance is necessary at Stationers' Hall to effect registration. It cannot be done by letter. Send to our publisher a copy of each print, with full details of title of picture, name of photographer, name of proprietor of copy, &c., with 1s. 6d. for each picture, and he will get the registration effected for you.

INEXPERIENCED AMATEUR.—Transparent spots are of many kinds, the most common being known as pinholes. Their causes are various, and have been much discussed of late in our pages. One of the most common causes is excess of iodide of silver in the bath. To remove this, pour the silver solution into double its bulk of distilled water, and then filter and make up the proper strength by adding nitrate of silver. The addition of two or three grains of nitrate of baryta to each ounce of solution sometimes proves a remedy.

IVORYTYPE.—The name has been given to various kinds of prints, but chiefly to prints made transparent and coloured at the back. It is not properly applied to pictures on opal glass. The two kinds of opal glass you describe are known as flashed glass and pot metal. The pot metal consists of opal material throughout its whole substance, whilst the flashed glass has only a surface coating of white glass or porcelain. The former, being translucent, gives a peculiar softness and somewhat sunken effect to the image. The glass termed cryolite is of American manufacture, where the material is found. The glass is produced in Philadelphia under the name of "hot cast porcelain," and, when made of pure cryolite, is milky-white in hue, and slightly transparent. Impure cryolite yields an opaque glass, closely resembling marble. The mixture for milky glass consists of—

Oxide of zinc	1 part
Cryolite	4 parts
Sand	10 "

This is melted in pipe-clay pots, which are not attacked by the fluo-silicic acid disengaged. The glass is very hard, remarkably solid, and is not attacked by strong acids, even when pulverized. These properties are doubtless due to the presence of undecomposed cryolite. With a small quantity of the mineral the glass is brilliant, and refracts light strongly; with a greater quantity it becomes opalescent; and, finally, on more cryolite being added, the glass turns opaque, and closely resembles porcelain.

J. GREEN, JUN.—As a non-member, you will have to pay a small charge for wall space. You will find particulars on another page.

PEARL-WHITE ALBUMENIZED PAPER.—We have received from Messrs. D. H. Cussons and Co. a sample of a very pretty albumenized paper, of which we shall have something to say in our next; as also of the Japanese cabinets designed as photographic accessories.

A. W. T.—You will find details of our own early method fully given in the *Year-Book* for 1866. In the volume of the *News* for last year, p. 196, there is a method, apparently a good one, described by M. Geyner.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. GELATINO-BROMIDE AND BICHROMATED GELATINES—THE ANNUAL EXHIBITION AND ITS REGULATIONS.

Gelatino-Bromide and Bichromated Gelatines.—There is a good deal of analogy between the exposure to light of gelatino-bromide and bichromated gelatine; that is to say, you are always in the dark—metaphorically speaking, of course—when you expose the first piece of carbon tissue or gelatine plate. In both cases you require a trial to test the light, and will require such trial until the time arrives when we are in possession of a delicate photometer, and have been able to fix upon a unit of light. If you ask a practised carbon printer how he decides upon the strength of the negative he is printing, and the number of tints that should be given, he will probably be unable to tell you; and although he produces a good picture, cannot lay down the law whereby another is to be secured. There is a good deal of groping in the dark, and, perhaps, some trust in Providence, in carbon printing, and it certainly is the same with gelatino-bromide. We do not know whether the latter varies in its sensitiveness day by day, according as it has been kept and according as the weather is moist or dry, as the gelatine tissue does, but we should think it very likely, and hence the photographer, like the student of algebra, has very often to work with two unknown quantities—the variation of light, and variation of sensitiveness. In our experience there is no better guide, both for the exposure and development of gelatino-bromide, than the treatment of a trial plate, just as a carbon printer begins his daily work with the development of an experimental bit of tissue. There is so much of the “*tuttoner*” element about the treatment of a gelatine plate in the dark room, that a guide of the slenderest nature is eagerly grasped. Mr. Mayland and Mr. Robinson, both of whom work the gelatine process with marked success, frankly admit that, like a clever, wayward child, they are bound to let the plate behave pretty much as it likes, and have to trust to its “broughtings up” to go straight and do the proper thing. You must be careful to do your duty, and the plate will then perform its obligation. The question as to the definition of foliage by a gelatine plate must remain an open question until we have learnt more about the film, for in the delicate matter of detail in shadows, the action of the developer is of considerable influence. But we must not forget this: that the gelatino-bromide gives more detail of the red end of the spectrum than the ordinary wet plate, and should, therefore, be more rather than less sensitive to the action of green leaves. For ourselves, we must admit, that in comparison made as quickly as possible one after another with wet plate and gelatino-bromide, the advantage, as regards detail in shadow, rested with the former; but then the superiority may have been due to the circumstance that we ourselves were more familiar with the working of one than the other. We repeat, we are, as yet, so much in the dark in developing a gelatine plate, that we should be careful how we lay down the law upon immature experience. Certainly, the makers of commercial plates have done their duty, and can scarcely do more for us. We get clear, brilliant films, and with an exposure that is wonderfully brief. We have secured a 10 by 8 landscape plate with half a second's exposure, using Dallmeyer's triplet, and have been compelled to dilute the ordinary Swan developer by half, for most of our work, so rapidly did the image spring up into being. For all that, however, gelatine films are not yet upon a satisfactory footing, not because of their imperfections, but because of ours. The taking of a trial plate is but a poor and clumsy expedient, after all, and photographers are in the same position as our engineers would have been had not the

electric telegraph been introduced at the same time as railways. We want a telegraph now to tell us something about the rapid goings on in the gelatine plate, and that telegraph is a delicate photometer by which we can measure the strength of daylight to a degree. Here is a field of investigation for the physicist, and one that ought to repay working, for could the photographer once get to know accurately the strength of daylight, one of the main difficulties connected with these rapid plates would be surmounted.

The Annual Exhibition and its Regulations.—We notice the Photographic Society will admit this year to their Exhibition “photographs coloured by scientific or mechanical means.” Opinions will be divided on the wisdom of this innovation, but we hope, at any rate, that the hanging committee will rapidly exclude everything of the nature that has not an essential novelty or element of excellence to recommend it. There are so many “processes” of colouring vamped up now-a-days that we fear the authorities will find their labour materially increased by opening the door at all. At the same time, the Society is acting more sensibly than it did last year, when coloured photography was said to be prohibited altogether, and yet admitted to the best part of the Exhibition. The vestibule and entrance to the large hall was hung with coloured photographs, to the astonishment of members as they tramped up stairs—pictures, too, which had been refused at a previous exhibition. The jury that has been nominated will, we think, command entire satisfaction. The painters, Mr. Marks and Mr. Oules, could not have been better selected. They are both what may be termed photographic, or life painters, and as such should be admirably fitted to judge camera work. Mr. Marks' character pictures and groups prove him to be a master in posing and in seizing distinctive features in mankind, while Mr. Oules's fame as a portrait painter is such as no one can gainsay. We are glad also to see that the Exhibition Committee have decided to allow themselves more time for hanging and cataloguing. It has been the rule hitherto to allow less than a week for these important duties, and the consequence is, that at the last a very great deal of work had to be performed at high pressure. This year, however, the last day named for receiving pictures is a Friday, while the soiree of the Society on the occasion of the opening falls on a Saturday. Usually, as our readers are aware, the day of opening was on a Tuesday, but we are not sure that a more popular gathering will not be secured on a Saturday; the main objection to altering the day seems to us that it changes the official one, which has always been a Tuesday. The name of exhibitor and the subject of the picture will be permitted on each frame, “neatly inscribed,” but no address, or anything in the shape of an advertisement, will be permitted. Those who intend to exhibit should, moreover, remember that there is very little time at their disposal. Scarcely six weeks will elapse before the 26th of next month, when pictures have to be delivered; and as there have been of past years more pictures than space allows for, some must inevitably be rejected, so that late comers will stand no chance at all. We have only to express a hope that the photographers of Great Britain will do their utmost to make the gathering a success, and that our friends in Europe who have so often lighted up our Exhibition with their work will assist us this autumn once again.

ON THE PRODUCTION OF COLOURED SPECTRA BY LIGHT.

BY CAPTAIN ABNEY, R.E., F.R.S.*

LAST year I incidentally mentioned in a note to the Royal Society (Proceedings, vol. xxvii., page 291) that the production of natural colours by the agency of light, examples

* A paper read before the Royal Society, June 19, 1879.

of which were shown by Becquerel, was probably caused by the oxidation of silver compounds employed. I have ventured to return to the subject in order to show that the colours are so produced, and are not due to interference.

I have sent, for the Society's inspection, pictures of the solar spectrum on silver plates, and also on compounds of silver held *in situ* by collodion. It will be observed that the spectrum has imprinted itself in approximately its natural colours; that on the silver plates it is more brilliant than on the collodion film, but that in the latter the colours are seen by transmitted as well as by reflected light.

I reserve for the present the exact details of the production of these pictures, but may say that they are produced by oxidation of silver compounds when placed in the spectrum: an exposure of two minutes being amply sufficient with a wide slit to impress the colours. The colouring matter seems to be due to a mixture of two different sizes of molecules of the same chemical composition, one of which absorbs at the blue end and the other at the red end of the spectrum, and the sizes of these molecules are unalterable whilst exposed to the same wave-lengths as those by which they were produced. I believe it possible and probable that the colours may be preserved unchanged when exposed to ordinary daylight.

THOUGHTS ABOUT THE NEXT EXHIBITION.

BY EDWIN COCKING.*

THE Annual Exhibition of the Photographic Society of Great Britain is so important in its bearing and results upon the outside world, that no efforts ought to be spared by the exponents of our art-science to render it so attractive that it should be as well visited as those exhibitions which are devoted to the higher branches of fine art.

To this end I propose making some observations containing hints and suggestions towards a further development of the resources of which we as a body are capable, and by which I believe we can make our Exhibition more entertaining.

In the first place, then, I would suggest that photographers should not so persistently devote their energies and skill to the production of what may be called set pieces, by which I mean a picture containing some special object as the central point of interest, which may be in itself totally deficient of artistic beauty.

I would suggest that more attention be given to the production of pictures affording a greater degree of artistic skill in the choice of subject and point of view. Our country is full of choice bits of foliage, and combinations of small growth of underwood, which, when studied as to the most effective lighting, would produce most charming and beautiful results. I think very much could be done in an instructional direction by the dissemination of successive stages in the growth and gradual attainment to perfection of our trees, and in combinations of foliage and the simple grasses which our country lanes exhibit; also in the distinctive beauty of form which flowers possess in almost endless variety, and in the grouping together of fruit and flowers, which are always pleasing when tastefully done. At the present moment the introduction of rapid processes should induce the attempt to perpetuate some of those evanescent, but at the same time most charming effects of light and shade which are ever to be found in our own land, and which arise from the constant variation in our atmosphere produced by passing clouds and other conditions of aerial transitions. Then, again, we should endeavour to get away from the routine of fixed sizes, which, like an iron vice, holds us in its grasp. A certain sized glass is used, and every subject

(whatever its individuality) must appear in that proportion. Now this is a matter which should demand the earnest thought, and bring out the latent artistic feeling of all photographers; for oftentimes a bit of a subject which, on a 10 by 8 glass, would be lost and utterly overlooked, would, if cut down to show its merits, become quite a totally different picture.

Another very important matter is the universal absence of figures in our photographic landscapes. In going through an exhibition of pictures, the emotions require quite as much food as the mind, and the public invariably respond to any appeal, however slight it may be, which enlists their sympathies; hence we ought to devise some means whereby figures or some human interest can be introduced into out-door photography. There are so many plans now in circulation to effect the introduction of subjects not taken in the original negative, that there should not be any necessity to hold back from experimenting in this direction. If a little more trouble and pains were expended on the introduction of figures, both human and animal, into many of our photographic productions, a very wide field would be opened for the exercise of latent skill on one side, and for a greater appreciation by the public on the other.

Too much is thought of the "oneness" of the means of producing a photographic picture, as if the ultimate result, both for the picture produced and the general public, consisted in its merit of being all done under one operation. We must get into the habit of looking at the "end," and not the means employed. As well might we distinguish between a picture taken on plate glass or on the commonest glass.

Then with respect to portraiture, how often is the remark made by thoughtful people that in looking at a collection of photographic portraits a feeling creeps over them that, although taken from nature, there is a great want of *naturalness* about them. I think that much of this feeling arises from the giving way too much to the supposed necessities of the tools we work with, viz., the lenses in requiring a complete flat field, we are so careful not to exceed certain bounds, that we thus get into a set way of confining all positions to this normal condition, whereas a little deviation from it, one way or another, is really of very little importance. If this be recognized, much more could be done in the direction of posing than has hitherto been the case.

Then, again, with the background. It is so easy to work with a plain dark background, that a vast of monotony arises from it. It has been said that in the regions of fine art the painter has derived a great impetus from the contemplation of the works of photographers. This is quite correct, for there was nothing before the advent of photography which gave to the appreciative student in art so much of the correct relative proportions of a figure, without the trouble of hard work and expenditure of valuable time in delineating the same. Artists having constantly before them these manifold revelations of the true, have engrafted that knowledge on their own perceptions, and therefore we now see detail in everything pictorial—one of the most distinctive marks of art in the present time.

But then, on the other hand, cannot photographers learn something from the study of what the painters are doing? I would especially call attention to the portraits in the present Exhibition of the Royal Academy; more especially to the backgrounds, which are becoming more and more unlike those of former years, when nothing but gloom and opacity surrounded the head. Now no hesitation is felt in introducing a variety of subjects as backgrounds; more especially foliage, which enables the artist to get more freedom of treatment in relation to the head.

In photography this could only be carried out either by a series of painted backgrounds executed by competent

* *Photographic Journal.*

artists (painted with the lights coming in from certain angles, so that the photographer could always adapt the background, or any part of the same, to the particular way in which he was lighting his sitter) or from negatives.

Then, again, there are very few attempts made in the production of pictures from costumes of various epochs, which in themselves possess most attractive qualities, both as to picturesque arrangement and effect of light and shade. Here, again, it is said the difficulty arises of getting a model to completely harmonize with the costume; but this is the very thing that ought to engage the attention of the photographer. He should find and adapt people as models, and exercise his latent perceptions in gaining experience as to what types and forms of figures and facial expressions arise from differences of structural conformation.

The photographer is not like the painter, who supplies from his own ideality any deficiencies of his model, but he is compelled to have everything before him before he can make an attempt at fixing the scene by chemical means; hence all must be well arranged and studied beforehand.

Photography must come to this some time or another, and all who can in any way stir up others to essay such experiments, or who can assist by hints and suggestions, will be helping on the progress of our art science, which, although dependent, to a certain extent, upon good tools (and therefore all steps in that direction are most valuable, and to be highly appreciated), must ultimately rest for due appreciation on its appeal to cultivated thought and feeling.

My object has been to set photographers thinking more of the artistic capabilities of their art science, which, after all, must be the side from whence the general public can understand and appreciate their productions; and it is just this quality which year after year we desire to see more cultivated, and I think it is only by exhibiting such works at our Annual Exhibition that we can hope to attain to the notoriety and consequent popularity which in the present day so quickly follow upon the exhibition of what is beautiful and artistic.

PHOTOGRAPHY AS APPLIED TO THE REPRODUCTION OF PLANS AND DRAWINGS.

BY DAVID TOWNSEND, B.S.*

(5) *Toning*.—By toning we mean giving colour or tone to the picture. The chemical theory is somewhat complicated, but depends principally upon the fact that when a neutral solution of some metallic chloride, such as gold or platinum, comes in contact with the washed print the chlorine leaves the gold and combines with silver, thus forming a deposit of gold on the picture. The chloride of gold is generally used for this purpose, and a normal solution is made by dissolving—

Chloride of gold and sodium ... 1 part
In dist. water 50 parts

This is kept in a bottle, and for every sheet of 20 by 24 in., 3 cc. are taken and mixed with 300 cc. of the following solution:—

Borax 1 part
Water 150 parts

It is sometimes convenient to keep a toning bath made up which can be used a number of times; in this case it should consist of—

Chloride of gold 1 part
Chloride of calcium 1.4 "
Water 4.564 parts

A little gold should be added from time to time, as the bath becomes exhausted. As nothing but small prints will require toning, a suitable porcelain dish should be provided and kept solely for this purpose.

(6) *Washing*.—This washing is merely to remove surplus toning solution, and is not very important. Five minutes in running water will be sufficient, and the waste need not be saved, as it is too dilute to pay for the trouble of extracting the silver.

(7) *Fixing*.—After removing all metallic salts, soluble in water, by washing, it is next necessary to dissolve out those still insoluble and remaining in the parts unacted upon, so that when the picture is finished and brought into the light, no change will take place. The solvent generally used is hyposulphite of sodium, or "hypo" solution, as it is technically termed. This salt has a peculiarity which should be remembered, namely, when in excess it acts as a solvent for salts of silver, but when the latter are in excess, the silver is precipitated as sulphide, which, when in contact with the paper, becomes black and insoluble. Great care must therefore be taken to have the hands perfectly free from "hypo," when silvering the paper or in afterwards handling it, otherwise black spots and finger marks will be produced. The fixing bath consists of—

a.—Hypsulphite of soda (Na₂S₂O₃) ... 1 part
Water 10 parts
Concentrated ammonia ½ part
Or,

b.—Saturated solution of hyposulphite ... 1 part
Water 8 parts
Saturated solution bicarbonate of soda... ¼ part

The alkali in both cases is used to neutralize any free acid in the solution, which would otherwise liberate sulphur and produce black spots on the print. I think formula (b) is preferable to formula (a), because the ammonium in the latter causes the paper to become very tender, and it is much more easily torn. The solution is put in a pan kept especially for the purpose, and the washed print transferred by taking two corners and lifting it carefully from the surface of the water. It is then let down as quickly as possible, and speedily covered on all parts with the fixing solution being careful to remove all bubbles. It is allowed to remain completely immersed for eight to ten minutes in warm weather, but if the bath is cold, a much longer time will be required. When the paper looks transparent the fixing is finished. The prints fade considerably in this bath, but regain some of their colour when washed and dried. The fixing solution must now be removed from the paper, or it will dissolve the image, and this is accomplished by the last operation to which the paper is subjected, namely—

(8) *Final Washing*.—The print, which is now very tender, is taken by the two shortest corners and raised off the fixing bath; it is allowed to drain thus for a short time, and is then carried to a pan kept especially for this purpose. The thoroughness with which this washing is performed will determine the durability of the picture. The prints cannot be washed too long, it being customary in photographic establishments to leave them in water all night; but for drawings, if the water be completely changed eight or ten times, it will suffice. In any case, let them be washed as long as the time will allow. The print is then removed and pressed between blotting-papers, which absorb all the surface moisture and make the print much lighter. It is now carried into a light room free from dust, suspended from a line by a spring clip, and left until dry. Care must be taken not to tear the paper, and thus spoil the work. When dry, the print is removed and trimmed, and is considered finished. The pieces of paper and trimmings should be preserved, as they contain silver, which may be extracted, or sold to dealers, who give nitrate of silver in return.

I have described this process at some length, believing it the best that can be adopted. It has numerous advantages, which will recommend themselves to all having much copying work to do. It is true, first cost is against it, but the results, especially for large work, are the best that can be obtained from any of the processes. We will now pass on to other methods.

(To be continued.)

* Continued from page 364.

MR. SWAN'S QUICK-ACTING ELECTRIC LENS SHUTTER.

CAMERON SWAN writes to the *English Mechanic* as follows :
 "As some of your correspondents have asked for an account of an instantaneous lens shutter, I will endeavour to describe one, invented and used by my father. The construction will be best understood by reference to the following diagrams :—

- A is the shutter box which screws on to the lens.
- B is the camera.
- C the electro-magnets.
- D the iron with the two notches in it, in which rest the pins which support the shutters.
- E the spiral spring.
- F the upper notch, which, when the current is not passing, does not support the shutter, which is supported by the lower one; but when the current passes, the notch supports the top shutter; the lower notch (F') which, when the current is passing, releases the lower pin in the lower shutter, and lets the shutter fall; but when no current passes, the upper shutter is supported.
- G is a lens screen made of brass.
- H is the part of the shutter which runs in the guide.
- I is a groove in the box.
- J J are the wires to battery.
- K is a piece of wire to push the shutters up with.
- L is the uppermost shutter.
- M is the lower shutter, made of thick cardboard, covered with a solution of lampblack and varnish.

The shutter apparatus is enclosed in a box made of fine cedar wood, which has an arrangement to enable it to be screwed on to the lens of the camera with which an instan-

aneous picture is to be made. Inside this box are two shutters or screens, which slide up and down inside the box, and run in grooves, well blackleaded to prevent friction. A groove is cut through on the outside of the box, and to one side of it an electro-magnet is screwed, connected to a battery, the wires from which are furnished with a touch-button, in order to make and break the current. Working on a pivot, opposite to the electro-magnets, is a piece of iron (D) with two notches (F and F') cut in the lower part of it, and in these notches fit two small pins, which keep the shutters from falling; and a spring (E) is connected with the lower part of D, the piece of iron, and keeps it away from the electro-magnets when the current is not passing. When the touch-button is pushed, the current passes, and lets fall the lower shutter by drawing away the prop (F'); and while the current passes another prop (F) is put under the upper shutter (L'). But as soon as the current does not circulate in the magnets, the spring (E) asserts its power by pulling away the other prop, and letting the top shutters fall and cover the mouth of the lens.

ON THE MAIN DIFFICULTIES OF THE CARBON PROCESS.

BY D. VAN MONCKHOVEN.*

MANY photographers who begin working the carbon process obtain generally good results at first, and then, when they meet with difficulties which they do not succeed in overcoming, give it up. There is no process, however, which is as simple and as easy, when a knowledge is obtained of the means of overcoming the difficulties it presents. I will give here some of the main points to be observed to insure complete success.

The Negatives.—The negatives used for printing in carbon should not be very intense in warm climates, and can be much more so in cold climates, for the following reasons. All negatives, thin or vigorous, within certain limits, can yield good carbon prints when the strength of the bichromate solution is adapted to them. Thin negatives require a weak bichromate bath, as low as 1 or 1½ per cent., to yield vigorous prints. Now, the principal difficulties which the carbon printer meets with are the spontaneous insolubilization of the pigmented tissue, and reticulation. These defects are most often met when the bichromate solution is strong. In hot climates, thus, weak bichromate solution and thin negatives should be the rule.

For cold climates, there is an advantage in using strong negatives, because in winter, when the light is bad, strong bichromate solution can be used, and the printing can be done rapidly. I believe, however, that, take it all in all, thin negatives are to be preferred, because they can easily be retouched. With such negatives, a solution of one per cent., or even less, is of sufficient strength.

A well known photographer recently began printing in carbon. His negatives were very thin, and I recommended him to use a one per cent. bichromate solution. He had no difficulty whatever during the summer, and with him carbon printing works as regularly as silver printing did, and with results just as fine as those he used to obtain on albumen paper.

Formula for the Bichromate Solution.

For weak negatives use—

Bichromate of potash	...	1 to 1½ ounces
Cold water	...	100 "

For strong negatives use from 1½ to 3 ounces of bichromate. In winter add one drachm of carbonate of ammonia, and in summer two drachms. This addition is indispensable, unless one uses the pure chromate. The ammonia makes the solution alkaline, and does not combine, as it was supposed, with the chromic acid. Alkaline solutions are indispensable in the carbon process, for acid solutions cause the tissue to become insoluble.

* *Practical Photographer Almanac.*

In summer, during the hot weather, change the bath twice a week, even if it should not be used every day. Old baths yield weak and flat prints. It may happen that a photographer succeeds with an old bath, but it may give away all at once, and then he finds that the tissue does not adhere, the prints are weak, and he is at a loss for a remedy. A new bath is made, and everything works right.

The bichromate solution should be kept cool, and should be filtered before use. The sensitizing, also, should be done in a cool place. The paper should be kept in the solution about three minutes, and should then be laid on a glass and squeezed lightly to get rid of the excess of liquid. If the squeegee is used too vigorously, there will be a loss of the half-tones in developing. The removing of an excess of solution is principally recommended in summer, otherwise the gelatine is apt to soften and to run.

If the tissue is left too short a time in the bichromate solution, the action is unequal, and the prints are covered with waves. If the heat is so great that the gelatine shows a tendency to run, lay the tissue flat on a cardboard, and allow it to dry in that position. You can also put it in alcohol for two or three minutes, and then hang it up to dry. The alcohol can be used several times.

Dry the paper rapidly in a draught. This is an essential point. If the paper dries slowly, it becomes insoluble and does not adhere to the transfer paper or the opal glass, or in developing the image becomes detached in parts. It is also difficult to remove the original paper from the transfer, and the development requires very hot water. The gelatine has, in fact, become partly insoluble. This, one of the main difficulties connected with carbon printing, is avoided—first, by the use of weak bichromate solutions; second, by drying the paper in a draught. To establish a current of air in a room, make a fire in it (even in summer) and open the windows, when you can dry your paper during the night.

Reticulation.—Reticulation is produced principally in summer. It is a kind of grain or net-work which covers all or part of the print, and destroys all definition. To avoid it, use weak bichromate, and immerse in very cold water before transferring it to the glass. It is important that the absorption of the water by the gelatine should be slow, and the colder the water the slower the absorption. Have, also, an abundance of it, so that the tissue does not come in contact with the warm air. The water in which the collodionized glass or the transfer paper is dipped may be at the ordinary temperature. The temperature of the water in which the tissue is immersed previous to making the transfer should, in summer, be below 50°; for the temperature of the water absorbed in the texture of the tissue is raised by the tissue being exposed to the hot air.

Note by the Translator.—It is necessary that the reader should know that the process of fuming with ammonia is not used by European photographers, and that paper not fumed requires slightly more intense negatives. The thin negatives that the Doctor refers to are not as thin as those made by a large number of American photographers, who use the double gloss albumen paper, and fume their paper with ammonia.

CHANGES IN PHOTOGRAPHY.*

THE substitution of dry sensitive plates for the common wet plates has made great progress during the past year or so; the old cumbersome method of dipping a collodion-covered glass plate into water containing nitrate of silver, then taking the picture before the plate has time to get dry, is becoming obsolete both for indoor and outdoor work.

Dry plates, having a sensitiveness equal to or exceeding of wet plates, are now easily prepared, and their convenience and economy have been fully demonstrated. The travelling photographer no longer needs to load himself

down with water bottles, liquids, and bath apparatus. He simply provides a few slips of prepared dry glass, with which and a light camera he climbs to the difficult places and secures the views he wants. The gallery artist is no longer obliged to waste his business time in waiting for the preparation and development of wet plates after his customers have come; but he may now both prepare and develop the dry plates out of business hours, and thus attend to two or three times as many sitters as heretofore. These dry plates may be kept on hand ready for use for an indefinite period.

At the present time, gelatine is the base used as the skin with which to cover these plates. The gelatine is dissolved in warm water, bromide of ammonium is added, and the mixture is digested with heat. A solution of nitrate of silver is then added, and the mass is thoroughly mixed and cooked, being kept at a uniform moderate temperature for four or five days continuously. The mixture is then poured on the surface of the glass plates, dried in the dark, and the plates are ready for use. Such plates require an exposure of only two or three seconds in the camera in order to take the picture. If greater sensitiveness is wanted, then the gelatine silver mixture must be kept under heat for seven or eight days instead of four or five. This is a very curious fact. Why the sensitiveness is increased by prolonging the time of cooking has not yet been ascertained. The development of the picture is effected by the use of a solution of pyrogallic acid followed by a solution of ammonia and bromide of potassium. The results produced are said to be in all respects excellent.

SPIRIT PHOTOGRAPHS.*

FOR some time, a certain class of newspapers have abounded in marvellous tales of spirit photography, the work of a lady photographer of Rochester, N.Y., assisted, of course, by the ghosts of her clients' ancestors and departed friends.

Recently, two lady sitters were impressed by the old-fashioned yet familiar costume and aspect of the spirits attending them in their pictures; and set to work to trace their probable pre-spirit history in the pages of an old magazine for ladies. The search was successful, the original of one of the spirits proving to be an engraving entitled *Nourmahal*, and the other, *The Last Rose of Summer*. No doubt the spirits can give good reasons for masquerading in those particular costumes, but as yet they have failed to do so.

The photographs and engravings fell into the hands of a representative of the *Rochester Union*, who, in order to ascertain the process by which the ghostly picture was printed beside the sharply-defined portrait, submitted them to a photographer who does not deal in spirits. The process was practically illustrated, and explained as follows:—

A negative is first taken of the engraving. When the sitter comes for a picture the negative is turned the other side, the collodion put on, and the glass put in the camera. In this manner, the portrait of the sitter is on one side of the glass, and what is intended for the spirit on the other. When the negative comes to be printed, the paper is placed against the side of the glass having the portrait of the sitter, and exposed to the light. The spirit, being on the other side of the glass, has to strike through it, which gives it the hazy appearance, while the portrait, being on the other side next the light, comes out clearly defined. Any one who is desirous of doing so can test this for himself, and the illustration shown by the photographer explained the matter fully to the eyes of the inquiring newspaper man. The more artistic a photographer is, of course, the more unearthly he can make the work, and the gentleman in question said he could produce a picture of the most ghastly description.

THE BUSINESS OF PHOTOGRAPHY.

WHETHER photography be a fine art or not, it is certainly a business. And whilst it owes much of its initiative and much of its progress to amateurs, it is to its value as a business, as a means of making money, it owes its present influential position and the rapidity of its progress. In an article in one of our American contemporaries, the writer asks why so few photographers make money? We need not stay to consider the various causes he adduces, inasmuch as we are disposed to demur to the truth of the proposition involved in his question. It is quite possible that few photographers may become millionaires. As yet few photographers are in a position, it is true, to relate the old story of having reached London on foot at the age of twelve with twopence as sole capital, then entered a warehouse as errand boy, progressed through every position in the house, finishing as senior partner, and Lord Mayor of London! But there are many photographers who have acquired handsome competency upon which to retire, and still more who have made sufficient competency without any wish to retire. Probably there are very few cases indeed in which a photographer has earned less by the exercise of his business as a photographer, than he did by the trade or profession which he abandoned for photography. By the investment of a very small amount of capital, the exercise of a reasonable amount of photographic skill and artistic taste, and the use of ordinary business tact, many photographers have made very comfortable incomes, and some have made fortunes. Even in these days of general depression and active photographic competition, we know of illustrations of what we have just written. A case occurs to our memory—we mention no names, nor do we give any clue or indication—in which, in an establishment commenced within half-a-dozen years, a sum of little less than four hundred pounds was the amount of a recent week's income! The principal, it is true, is a gentleman of business tact and close personal application to business, as well as photographic ability. We mention the circumstance to illustrate the fact that at a period of unexampled photographic competition, and dullness generally, when no money is supposed to be stirring, it is possible, by the exercise of the proper qualities, to make very handsome incomes and accumulate fortunes in photography.

But to make money by the business of photography, it must be regarded as a business, and the same business tact and application, *mutatis mutandis*, will secure the same

results in this as in any other business. Our able correspondent signing his letters "Mass" has pointed out some sources of failure. He has insisted on the fact that small businesses do not pay; that, in other words, the attempt to establish a business without the fitting capital and appliances will not command business success. An operator is very naturally anxious to exercise his profession on his own account, and commences in a very small way. He practically, in fact, exchanges one employer for many. The public becomes his master, but he (the workman) must pay rent and provide appliances for conducting the business. In some cases, with great ability and much industry, and not a little privation, such an attempt to establish a business succeeds. Very often it fails, and the photographer lives a struggling life and becomes a soured man. We do not deprecate such attempts—scarcely so much, indeed, as we think "Mass" does. We think the attempt praiseworthy, and have every sympathy with it. But in attempting to establish a business in such conditions, especial care and skill are necessary to success, and special avoidance of the traceable causes of failure. We may mention a few of the latter. One of the most common causes of failure under such circumstances is yielding to the temptation to do a low-priced and necessarily common class of work. As a rule, low-priced work must be common. Materials and appliances generally must be common, and less fastidious care can be bestowed upon the work in all departments than can be given to work which is well paid for. Good work sent out is a perpetual recommendation, and the best aid towards forming a business; while poor work is seen and examined by many without any reference to price, and is therefore no recommendation. Another cause of failure to which some photographers are especially liable, especially those who very properly put a high estimate upon their profession, consists in unwillingness to see their sitters before sitting, to enter into business explanations. They feel that making any arrangement of a business nature is beneath the position of an artist, and leave such matters to the attendant in the reception room. This is very right. Such attendant is the proper person to make such arrangement. But there is a large class of sitters who are unwilling to be dealt with in this fashion. They have an invincible desire to see the principal, and make arrangements with him; and the photographer, if he possess skill and tact, may materially promote and cement his business connection by readily acceding to such desires amongst his sitters. Another of the causes of failure common to, and apt to be overlooked in, small, struggling businesses consists in a tendency to be negligent and slovenly in regard to specimens and show-cases. The cases and frames get old and shabby, the specimens old and out of date, and at times even a little faded. The entrance and reception room grow shabby and dusty, the latter suggesting its frequent use as a family sitting room as well as a reception room. It is surely barely necessary to name these things to point out that they are thoroughly in antagonism to the spirit of business, and a natural cause of business failure. Our correspondent, "Mass," says that small businesses do not pay. We think he is right. Even if carried on with perfect business care, they cannot pay as well as large businesses. But it is chiefly because they are especially subject to the causes of failure we have named, and others of a similar kind, that they are not only less profitable than large businesses, but that they are frequently failures. One of the prevalent faults in a small business is unpunctuality and delay in completing orders. An operator may be most skilful in photography and artistic in taste; but he may have no idea whatever of the importance of business punctuality; and the lack is fatal. Whether he commence business on his own account, or be the man-of-all-work in some small establishment, this unpunctuality in completing and sending home orders must prove fatal. We have known very capable photographers wreck their whole

fortunes on this rock, struggling on in shallows solely from this cause. Success depends upon attention to a number of trifles almost impossible to recount. A large number of these trifles are summed up in the word precision: precision as to time in sending home orders; precision in finishing work, and carrying out all details of instructions given. We have frequently asked successful photographers to what especial thing they owe their success. Unfortunately, the qualities which have secured success are often so natural to a man that he is scarcely conscious of them, and cannot often enumerate them. One very successful man said he thought it was partly due to being very fastidious, and never suffering a print to go out that did not please himself. This was one of the elements of the precision of which we speak. We have no intention, however, to write a didactic essay, but merely to recall a few hints which may be useful in connection with the subject.

MODIFICATIONS OF THE ALKALINE DEVELOPER.

THE effect of varying the proportion of pyrogallic acid does not seem to have obtained sufficient attention in the use of alkaline developing solutions. It has certainly been less regarded than it used to be in the old acid developers. We remember some instantaneous negatives on Fothergill plates, which were developed with a twelve-grain pyro-solution, containing also four grains of gallic acid. Col. Stuart Wortley has often insisted on the importance of increasing the proportion of pyro in securing intensity. He has recently communicated to the Society's Journal details of an article on the subject which was printed in one of the journals in 1874. He says:—

"The difference to be found in the use of developers of various strengths is a subject to which sufficient prominence has not hitherto been given; and while much has been written on the component parts of an emulsion, but little notice has been taken of the fact that with the same emulsion, or same bath process, an endless variety of negatives or transparencies can be produced, and thus to those who use a strong alkaline developer the following hints will be of use:—

"If your negatives are coming too dense, reduce the amount of pyrogallic acid in your developer; if your plates, on the contrary, are wanting in density, increase the strength of the pyrogallic acid, adding, in the latter case, a drop or two more bromide to control the increased energy of the developer.

"The plate is very nearly as sensitive with a weak solution of pyro as with a strong one, and the development is under great control, as by adding a few drops of pyro, from time to time (having commenced with the maximum of strong ammonia), the plate can be worked up to any required density. When liquid ammonia is used in the developer, the pyro and bromide should be applied to the plates before adding the ammonia to the developing solution.

"A modification that I have found of great value during the past summer has been the use of a preparation of gelatine in the alkaline developer. It enables one greatly to reduce the amount of bromide, and indeed, if necessary, to dispense with it altogether, as the gelatine has a great restraining power over the action of the ammonia, and does not, as bromide does, interfere with the production of detail. Gelatine also gives a beautiful deposit on the negative, and anyone having once used gelatine will, I think, adopt it for his future work.

"Tannin and gallic acid can also be used in the developer to replace bromide; but the quality and character of a negative developed with gelatine make me prefer that substance to either of the two last mentioned. You will remember that when gelatine was added to the iron developer some years since, it tended to produce a harder and denser negative than one developed with the ordinary iron developer, and, moreover, the plate required a longer exposure in the camera.

The action of gelatine in the alkaline developer is, as nearly as possible, the reverse of all these conditions.

"Another subject which I worked out is fuming by ammonia as a means of developing dry plates, and with the gelatino-bromide process I find great advantage in its use.

"The less a gelatine film has to do with water the better; and I prefer to develop a gelatino-bromide plate by pouring on it, to commence with, a developer composed of glycerine and water, or gelatine and water, and to which the necessary bromide and pyrogallic acid are added as usual. It is then put into the box and fumed, and a brilliant and perfect image very rapidly appears."

BLOOD ALBUMEN ON FOREIGN PAPER.

FOR some time past rumours have been rife to the effect that blood albumen was used in preparing some foreign photographic papers, and that various printing difficulties and final fading were the result. We have received various letters asking if it were true that blood albumen was used instead of egg albumen, and on one occasion we received a very abusive letter from the agent of a foreign house for having allowed an allusion to "such an absurd impossibility," as he alleged this to be. We have no means whatever of investigating the practices of manufacturing houses in preparing albumenized paper or other photographic materials; but we may remark that if blood albumen were used we have no reason to believe that the paper would be in any way the worse for it. Egg albumen and blood albumen are chemically and physically identical, a little deeper colour being the only distinction of the latter. Some remarks at a meeting of the Chicago Society by the Secretary will interest our readers:—

"Some time ago, in the published minutes of one of the German societies, I saw a brief mention by one of the members of a suspicion that some of the manufacturers of albumen paper were serving the photographers with blood albumen, and possibly some of the troubles we were having might be laid to this cause. I gave the matter some little thought, and as I could find nothing published giving any light on the nature of this blood albumen, I thought it might be well to investigate a little. As a great deal of complaint had been made about the Dresden extra-brilliant paper under its various marks, I turned my attention particularly to this manufacture. I gave a sample to Dr. Piper, asking him to tell me whether it was egg or blood albumen. I also interviewed Professor Hirsch, who is engaged largely in making this blood albumen for the use of calico-makers and book-binders, his firm buying all the blood from the slaughter-houses at our stock-yards for this purpose. Professor Hirsch examined the paper, and pronounced it blood albumen. I saw Professor Siebel, a chemist, and he said the only sure way was to get a proper analysis made, which he would undertake for the Society at the cost of time and material, probably ten dollars. Nothing was to be had in the line of information as to the chemistry of this blood albumen, or whether it was of a nature that would cause any of the troubles we were having with albumen paper. I wrote to Mr. Bode, of Milwaukee, who has done so much for us in chemical investigations, and here is what he says in regard to blood albumen: The detection of blood in albumen paper is a very difficult matter. Egg and blood albumen are chemically the same, and can only be recognized by optical analysis. This requires an apparatus for polarization. If Professor Piper declares the sample you gave him to be blood albumen, it is undoubtedly so, as he is an authority in microscopical and optical analysis. Another question is, whether the blood albumen is not as good as egg albumen for making the paper; and I think, if of the proper purity, it will be just as good. The smell is no means of recognizing the blood albumen on the paper, as egg albumen smells just as bad when spoiled through dampness. I have had considerable trouble this winter with the foreign papers, but the dissolving of the albumen could hardly come from the blood albumen, but it might be that manufacturers use something else to

cheapen the paper (blood albumen, of sufficient purity, has a high price); for instance, gelatine, which would account for the easy dissolving qualities of the albumen. The matter has been discussed at the meetings of the Berlin Association, the trouble of the softening of the albumen being laid to the low temperature of the silver solution, the atmosphere of the drying-room, and the freezing of the albumen on the paper. Herr Rolaff stated that, on good authority, he had learned that gelatine was used in the preparation."

FRENCH CORRESPONDENCE.

REMARKS ON THE PAPER BY DR. VAN MONCKHOVEN ON GELATINO-BROMIDE OF SILVER—APPOINTMENT OF A PROFESSOR FOR THE COURSE OF LECTURES ON THE INDUSTRIAL REPRODUCTION OF WORKS OF ART AT THE NATIONAL SCHOOL OF DECORATIVE ART AT PARIS.

The time has arrived when I have to ask myself how it is possible for me to write anything at all possessing interest when there is a complete dearth of photographic news, at the same time that I have fully determined not to say a word that can be construed into a criticism of anything or anybody. There are quite enough critics, discriminating and impartial as they may be, on the staff of the PHOTOGRAPHIC NEWS, that I, too, should enrol myself among their number; besides which, it is rather their judgment to which I ought to submit myself, than that I should be considered worthy of being myself a judge of others. The line of a foreign correspondent is very clearly traced; it consists in rendering an account of all the photographic occurrences of any real interest which may happen in the country where he lives, and it is in this respect that I feel myself on this occasion a defaulter. Not that I mean to say that in this great country of France photography is for a time absolutely dead; I have no reason to suppose that; but that I myself have no information. I have tried very hard, but without success, to learn or obtain information about something new; all my colleagues are away at their country residences, at the seaside, at the baths, or on their travels.

*Some Remarks on the Author of the Paper on Gelatino-Bromide read at the last Meeting of the Photographic Society of France.**—In speaking of my colleagues, I allude to those scientific photographers who work out improvements in the various methods: the absence of men of this description was marked at the last meeting of the Photographic Society of France, where, except for the co-operation of a Belgian scientist, Dr. Van Monckhoven, there would have been positively nothing of any importance commended to or shown at the meeting. Of the new process introduced to the notice of the photographic world on this occasion by my friend, Dr. Van Monckhoven, I shall say nothing until sufficient trial and practice have verified his assertions and proved that his claim to have made another step in advance in the path of the progress of the question of gelatino-bromide has been really established. As far as the principle of the process is concerned, I feel convinced that his intervention in this question, which is a capital one for the future of photography, can only have the effect of rendering it a signal service. Of course Van Monckhoven's work will be discussed, and it is possible that his assertions may be disproved; it is quite on the cards that what he has discovered will be declared to be not new, and that the results of his researches which he claims for himself will be maintained to have been found out and published by others long ago. But though all this should happen, it will not affect the utility of his communication, the great value of which will consist in attracting to the subject the attention of many persons, even though they approach it merely to criticise his work.

Van Monckhoven is a man of too much culture—he possesses a too true and profound knowledge of science—that anything he says should be passed by without notice. Among the scientific men and chemists of the entire world who have specially given their attention to photographic questions, are there many who can be compared to him in respect to ability, who are as well acquainted as he is with the details of this important subject? I shall not venture to mention the names of those who may be placed by the side of Van Monckhoven. I have known him for more than twenty years; and, as regards a friend of so long standing, I may be permitted to have a fixed opinion; whereas, as respects others with whom I am less intimately acquainted, I might very possibly be mistaken. But of this I am perfectly certain: that Van Monckhoven is one of the most distinguished scientific men of the day; that he possesses a natural intelligence cultivated to a high degree, united with a profound acquaintance, perfected by long practice, with photographic theories and processes. It is not a panegyric of my friend that I am here attempting, but rather a kind of portrait taken from the life. I have been induced to state my opinion of him by the fact of his having communicated a paper to the Photographic Society of France—a paper which, coming as it does from so high an authority, whatever may be its character, even supposing it to be fallacious (a supposition in this case perfectly impossible) deserves to be received with eagerness, and to be examined with care, not to be dropped as unimportant or wanting in interest. One must have known Van Monckhoven for some years to be able to appreciate his inexhaustible flow of ideas on scientific topics, the great facility he has of rendering himself master of a subject, his indomitable application, both of mind and body, to the work of experiment and research. One feels inclined to ask, how is it possible to develop so much mental and physical activity, to be always investigating, discovering, and producing? But however great may be the affection that I feel for this eminent man, in speaking of him I put our old friendship for each other entirely on one side; I forget the friend, and think only of the *savant* who has so greatly distinguished himself by his investigations in our art. He belongs to us because of the high position he occupies in the photographic world. We do not now review our friend Van Monckhoven, but the author, the chemist, the physicist, whose name has been for a long time enrolled in the list of those who pursue the science of photography, whose treatises were our first text-books, whose actual work is extensive and incessant. To those who discredit him—and there are such, for there is no man of any position alive who is free from attacks, sincere though they may be; besides which, perfection is not to be found in this world—to those who discredit him, I should reply, "Forget the faults you may see in him, and think only of the real and incontestable worth of a man so tenacious of purpose and persevering unto the end as he is. Is there not on the side of merit, on the side of learning, an amount of good, sufficient to weigh down all real defects, and even all suppositious errors? Which of us would stand sifting so well as the colleague of whom we are speaking? All our good qualities would pass through the sieve, but how large would be the share of our whims and of our ignorance that would remain on it! It will be said by those who see this enlogism on our friend that it reads as if drawn upon the occasion of his death. Thank God, there is no question of that; it is because Van Monckhoven is full of life and health, as his work proves, that I devote these lines to him. Besides, I have written them as they fell from the pen without any premeditation, for in commencing this letter I was in great doubt as to the subject on which it would turn. But I have taken the opportunity offered by the paper presented by my learned friend to the Photographic Society of France to say what I think of him. In doing this, I do not believe that I have transgressed the functions of a correspondent of a photo-

* See last week's PHOTOGRAPHIC NEWS, page 374.

graphic journal, for the subject of which I am treating forms absolutely a part of photographic science. Without touching in the slightest degree what may be called a personal question in the bad sense of the term, I have been led away, but without any attempt on my part to resist the feeling which prompted me, to write a eulogium of one of our best known fellow-workers—a eulogium which I believe to be fully deserved, and which I have no desire to weaken by any criticism. For the latter I should have had some trouble to find material, for knowing Van Monekhoven as I have done so intimately and for so long a time, I am better able than others who are not so well acquainted with him to form an opinion of his work. I have followed his career with sufficiently continuous attention to be in a position to appreciate it, and I do not hesitate to say that my illustrious colleague deserves to be placed in the highest rank of those who, by their knowledge, their discoveries, and their writings have most successfully cultivated the photographic art, and have most contributed to its extension and popularity.

Appointment of a Lecturer on the Industrial Production of Works of Art at the National School of Decorative Art.—And now, in concluding this letter, let me mention a fact which tends to show that the mind of our Government is being educated in the idea of establishing a system of instruction in photography. At the ceremony of the distribution of prizes to the pupils of the National School of Decorative Art, the Assistant Secretary of State, who presided on that occasion, announced the official organization of a course of Sunday lectures on the "Industrial Reproduction of Works of Art," and that the appointment of a professor to whom the duty of lecturing would be intrusted was about to be submitted to the Minister for approval and signature. I have on previous occasions mentioned, for the benefit of my readers in the PHOTOGRAPHIC NEWS, a similar course of lectures in which photography played a considerable part. I myself was the first lecturer so appointed, and now I am again called upon to continue a course of instruction which I hope to see introduced into all our Schools of Art. The fact, at any rate, is a fresh triumph for the science of photography, and an important recognition of its incontestable value.

LEON VIDAL.

A NOTE ON GELATINO-BROMIDE.

BY HENRY COOPER.

A good deal has been said lately about the difficulties of prolonged emulsification arising from the partial decomposition of the gelatine, and also from the peculiar change which long-continued or oft-repeated heat produces upon solutions of gelatine, whereby its setting properties are much impaired. During warm weather this latter defect becomes a serious drawback when we come to the coating and drying of the plates, and it is useless to attempt to overcome it by making the emulsion more concentrated so long as the ordinary method of washing is followed. Even in the state of jelly, gelatine will go on absorbing water, and will take up such a quantity during the washing as to materially dilute the emulsion. Besides, it is not well to form the bromide of silver in too viscid a solution.

For some time past I have successfully got over both the above-mentioned difficulties by employing the following method, and, so far as I can at present see, without any drawbacks. The proportions are Mr. Bennett's:—

Twenty grains of Nelson's photographic gelatine are soaked in half an ounce of water containing two minims of pure carbolic acid, fourteen grains bromide of ammonium are added, and, after liquefaction, the solution is sensitized with twenty-two grains of nitrate of silver dissolved in half an ounce of distilled water. Cook for a week at 90°. Set, and wash in the coldest water obtainable; then add twenty grains

of the same gelatine in shreds, and raise the temperature to 90°, maintaining it until solution is effected. Then pour in one drachm of pure alcohol sixty over proof, and filter for use. If the finished emulsion is to be kept for any length of time, two minims of carbolic acid may be dissolved in the alcohol.

It will be noticed that carbolic acid is used in the first instance to prevent putrefaction during the week's emulsification, and further, that one-half only of the gelatine is submitted to this risk, the other half being added after washing, and thereby escaping the prolonged heating.

Another important point is that the finished emulsion contains only half the quantity of water ordered by Mr. Bennett, and in consequence will set much more quickly and firmly on the plates, which may be dried at a higher temperature than otherwise possible, unless they remained in a perfectly level position until dry.

The plan just described is, I believe, a good one, and of course variations in the proportion of gelatine left out may easily be made to suit different conditions of working. One point to be remembered is, to have twenty grains of gelatine to each ounce of water in the first emulsion.

Before concluding this short "note," I will briefly describe my method of coating the plates during warm weather. I obtained a large dish (mine is zinc, and measures 26 by 20 inches), and had a sheet of plate glass cut a little smaller (24 by 18). When about to prepare a batch of plates, I place the plate glass in the dish, and with four wooden wedges level it, leaving a space of about one inch under the glass. Cold water, containing crushed ice or freezing powders, is now poured into the dish until it touches the under surface of the glass. As each plate is coated it is laid upon the chilled surface of the plate glass until set, and then reared up on end in the drying cupboard just as if it were a collodion film. A flat cover, resting on the sides of the dish, prevents any light falling on the films whilst they are setting.

In coating the plate it is not warmed, as I find the emulsion will flow rapidly over it, quite up to the edges, if the plate be breathed upon. If anything is ever needed to guide the flow of the solution, I prefer a scrap of clean paper to anything else.

The thanks of all gelatine workers are due to Mr. Mawdesley for his plan of soaking the plate in chrome alum before development, as I think it will prove efficacious in almost every case, if two precautions are taken. First, the solution must be strong enough, and it must be as cold as possible. The wash waters and the developer itself will often need chilling during warm weather, if the films show much tendency to filling.

I have lately had to use as much as three grains of chrome alum to the ounce of water, and this has been done without any injurious effect upon the sensitiveness of the film.

As the temperature of my own room varies from 70 to 75°, I have just now all the miseries of warm weather without its delights, and am well able to test various methods for overcoming the difficulties of summer work with gelatine.

One word more, to call attention to a method of reducing over-intensity which has just been referred to by more than one writer. I allude to the use of a weak solution of cyanide of potassium containing iodine. For nearly a year this has been my favourite method, and I intended many times to write a note on the subject. I dissolve iodine in iodide of potassium (strength of solution immaterial), and add sufficient of a solution of cyanide to render it colourless. A little more of the cyanide is then added, and the solution diluted for use. To render intensity locally, I mix this solution with gum-water, and apply with a camel-hair brush. I need hardly say care is necessary; but with it, I have found the method safe and effective.

The compound solution does not appear to keep well for any great length of time. I prefer to keep the iodine solution ready, and add the cyanide shortly before use.

A FEW MORE WORDS ABOUT GELATINE EMULSION.

BY PHOTO-CHEMISTS.

YOUR cruel correspondent "Kaleidoscope," in giving my suggestion of using an ink-bottle for preparing emulsion a "backhander," thinks that among the events "wildly possible," even the ginger-beer bottle may be found to have its use. Poor "Kaleidoscope"! he must have been "Rip Van Winkl-ing" with a vengeance. Let him condescend to look at an elementary work on photography, and he will find something as follows, *re* the toning bath:—"It should be kept in a stone bottle, to prevent access of light, which would soon deposit the gold." I hope he is now satisfied that it will be no use for him to patent the use of ginger-beer bottles in photography.

But "*revenons a nos*"—ink-bottles. I have again, since writing, gone through the whole process as described by me a week or two since, and am delighted with the extreme ease of it. The ink-bottle holds about seven ounces, and is furnished with a lip, which is a great advantage in pouring. Having made the emulsion, poured it into the ink bottle and tied it down, I placed it in the saucepan, and digested it for four days, or, more precisely, a hundred hours. Now, I have two suggestions for your readers. First, don't use gas; the pressure is frequently varying, and the heat often rises above that required. The night light answers admirably. I used a ten-hours' one, and placed it about two inches under the saucepan on the hob in my room. At bedtime, 11 p.m., I removed the old and put a new one, replacing this at 9 the following morning, and during the hundred hours' digesting I never found the heat vary more than three degrees from a temperature of ninety-five.

Now for my second suggestion. I very much doubt the necessity or advantage of the long emulsification. After the first twenty-four hours I coated a plate; when set, soaked it in cold water to wash it, and dried it: at fifty, eighty, and one hundred hours I repeated this. I then exposed the whole four under exact conditions as to light, time, and object, with the result of finding them alike, or, at all events, very nearly so.

Here is a heresy for you; and as backsliders rarely stop half way, I am prosecuting some experiments to prove that, delicate as gelatine plates undoubtedly are, they may be successfully worked without the very extreme precaution of filtering the light through two thicknesses of ruby glass, which deprives the operator of all control over development, and I hope shortly to give you the results at which I have arrived.

GUP.

It would take a long day's march, even among the back numbers of the PHOTOGRAPHIC NEWS, to find many collections of such interesting and instructive photographic information as was gathered together in the issue of last week.

Mr. Beatty's contribution, entitled "Some Historical Recollections of Photography," is one of no ordinary importance. There are but few living who can lay claim to two score years of photographic experience, and I trust there are none who can read Mr. Beatty's practical, straightforward narrative without peculiar interest. These personal reminiscences are worth more than any amount of clippings from the *Encyclopædia Britannica*, or *rechauffes* of Gaston Tissandier's History and Hand-book.

By the way, do photographers buy Tissandier's book as freely as they might? The elegant English edition, edited by Mr. J. Thomson, of China and Cyprus fame, and published by Low, Marston, and Co., is an ornament to any shelf. Some of the work, wood-cuts included, is a trifle

antiquated, but it contains much good matter nevertheless. The description of the early days of photography, of the labours of Daguerre, of Nicéphore, and of Isidore Nicépce, is really fascinating, both in point of interesting matter and of capital literary style.

Dr. Van Monckhoven's "new method of preparing gelatino-bromide of silver" demands concentrated attention from all. At the same time, I imagine that the manufacture of pure hydrobromic acid, and the concomitant calculations of quantity, will be a crux in the way of its universal adoption, even by the enthusiastic amateur. Dr. Van Monckhoven, however, promises the "minute details" in a future paper. If these tend to increased facility of operations, as well as to excellence and rapidity of results, "Kaleidoscope" will at once shut himself up in his dark room, and concoct gruesome messes and odours until he, too, can cry "Eureka!"

The way *not* to acquire an appetite for dinner: to take a protracted sniff at a decomposed solution of gelatine.

Captain Abney's process of making the bromide separately in gelatine emulsion does not seem to be attended with general success in other hands. I have got as far as the bromide, but, owing to repeated calls on my time, the emulsification has not yet come off. When it does, and if it succeeds, I shall hasten to record the fact, if only for self-satisfaction's sake, in having vanquished the difficulties which overthrew the veteran Dr. Van M.

I own that in spite of M. Versnaeyen's terse—and to others, perhaps, sufficiently lucid—report in last week's *Freuch Correspondence*, the "Kaleidoscopic" vision has only taken in a very general idea of M. Leon Vidal's new portable camera. I quite agree with M. Vidal that in the present focussing arrangements of cameras there is room for improvement; but I think if the ground glass could be replaced by some kind of cloth, the defect of breakability would be obviated more satisfactorily than by M. Vidal's method.

I never broke a focussing screen except once in my life, and that was some little time ago, in trying a gimcracky apparatus that looked as if to break at intervals, until a final collapse "chewed up" the whole concern was its natural end and aim.

And now I must weary my readers with a subject which, for me at least, has some small interest not wholly unmixed with amusement. In reply to a mention I had made in a former number of the *Photographic Artists' Co-Operative Supply Association*, Captain Kerr, as Managing Director, wrote last week to correct some misstatements which he thinks I have perpetrated. As a matter of fact, the only absolute misstatement was one relating to the address of the Association. For the address of the stores and offices, I through error gave that of the manufactory.

My remark about gentlemen playing at shop-keeping was purposely set up in a separate paragraph, and was merely offered as a general and by no means personal observation. If, however, the P. A. C. S. A. prefer to take it all to themselves, I dare say the other co-operative societies will entertain no objection.

Captain Kerr's remark that the P. A. C. S. A. neither pretend nor profess to be any other than ordinary traders, except as far as regards their working on the co-operative system, strikes me as being rather clever. A Dissenter, by consequence, is the moral of a Churchman, except so far as he goes to chapel instead of to church.

Captain Kerr nobly tells the Editor that if he sees anything unfair to competing traders in the P. A. C. S. A. he may allow me to point it out in the columns of the NEWS. Permit me to assure you, Captain Kerr, that if the

P. A. C. S. A. did contain any proven element of unfairness, your permission would not be asked to point it out in manner not admitting controversy, even from your facile pen.

As for leaving the P. A. C. S. A. to pursue the even tenor of its way untrammelled by prejudice, I have far too little interest in its existence to trouble my head further about the matter. If the Association can show by consistent rectitude and uprightness that it disdains either to obtain under another name goods otherwise unlikely to fall into its hands, or to entice shareholders by a fictitious business based on sacrificial underselling of other manufacturer's specialities, it need not fear to be trammelled by the "prejudices" even of

KALEIDOSCOPE.

NEW COPYING PROCESSES.

A CORRESPONDENT of the *English Mechanic* gives the following interesting details:—

"I lately purchased a 'chromograph,' which is apparently the original form of a new copying process. It was patented and made by a company, but, within a few days, I came across no less than four other close imitations, which were being freely sold under various names. I inquired about the validity of the patent, and could not get any very decided information. After a few minutes' search at the Patent Museum, I found a patent by J. G. Wilson, 13th November, 1878, No. 4601, which seemed to embody, at all events, the principle of this new process; but partly because imitations were being freely sold, and because the specification made no mention of several points about the article which are decided improvements, I felt no scruples in copying the receipt, from which some dozen or more have been made (for private use) by my friends.

"Take one part by weight of gelatine (glue does just as well), let it swell in two parts of water, melt, and add four parts of (common) glycerine with a few drops of carbolic acid, and sufficient whiting or white-lead to make the whole milky. Pour the mixture into a shallow tin or zinc dish; it will be ready for use in about twelve hours.

"I have not been successful with the ink prescribed in the specification: 1 violet methylated aniline (Hoffman's purple?), 7 distilled water, and 1 alcohol, so I have bought it at the most extravagant price of 1s. per ½-ounce bottle; but acetic rosaniline, boiled down in alcohol till it does not run in writing, forms a capital red ink. The purple ink is dosed with oil of almonds, I suppose, to mask its real composition.

To use the process, write on any kind of paper with the ink, taking care that the writing is thick enough to show a green lustre on drying. When dry, place it, face downwards, on the jelly, rub it gently to bring it well in contact, and leave for one or two minutes; then peel it off. It will leave a large portion of the ink neatly transferred to the jelly; then place the paper to be printed on the writing, and pass the hand over; bring it well into contact as before, peel it off, and it will bring away a perfect copy of the original. In this way sixty to eighty copies may be made; by using a thick pen and plenty of ink, one hundred good prints may be taken. If the original still shows a green lustre, another transfer may be made. When exhausted, wash off the ink from the jelly with a sponge and cold water; the ink need not be entirely removed, since it does no harm if too faint to print and the composition is worn away by washing; a layer a quarter inch thick would give five thousand copies at least, if not twice that number. If the jelly is injured, it may easily be melted down over a spirit lamp, or in an oven. After melting, and in the first instance after making, the surface should be washed with cold water.

I consider this to be one of the most important inventions made for some time, and it is a great pity that the inventor, a Bavarian gentleman, did not more carefully protect it, though it is very foolish to sell an article for 12s. 6d. when it can be made by anybody with the greatest ease for 2s. 6d.

"The use of the whiting or white-lead is to show up the writing on the composition, and to enable the washing off to be observed more easily. Neither this nor the carbolic acid are mentioned in the specification; but since so many slightly differing articles are being sold, I believe anybody is at liberty to make one. 12 inch by 10 inch is a convenient size. A pair of tablets this size is sold for 20s!"

Correspondence.

THE FERRO-CYANIDE DEVELOPER.

SIR,—The most recent contribution to our knowledge of dry plate working is Mr. Henderson's ferro-cyanide developer, and I think I may safely say, after giving it a very extended trial, that it entirely changes the whole aspect of affairs—there is a simplicity and certainty about it that enable almost any one to work it. Thus much might have been said for the ferrous-oxalate developer, but it was accompanied by such continual organic changes that considerable experience was required to follow them, and a tedious length of time occupied; but with the ferro-cyanide, a rapid, powerful, brilliant development, free from fog, is obtained.

Permit me, in a few words, to give what, in our own studio practice, is found to be very successful—

Sat. sol. fer. cyan. pot.	2 ounces
Water (ordinary)... ..	2 "
Pyro	8 grains

When about to use, add two drops ammonia for each ounce—the dark colour assumed by the liquid is unimportant—wet the plate under a tap first, and then immerse; full intensity, with abundant half-tone, is readily acquired. In such a quantity as given above (four ounces) several quarter-plates may be developed.

It must not be forgotten that a pinch of pyro and a drop or two of ammonia are wanted for each fresh plate. There is no doubt that this developer enables one to shorten the exposure, I think, about one-third.

It must not be overlooked that development should be continued till the draperies are nearly buried, otherwise the intensity will be insufficient. It is a great advantage of this developer that the negatives resemble wet collodion ones in every respect. If, from over-exposure, difficulty is found in getting intensity, an addition of pyro will give it; for more half-tone, or to bring out draperies, more ammonia is wanted.

The best way to mix pyro is to dissolve an ounce of it in two ounces spirit by pouring the spirit into the pyro bottle—six drops may be called a grain. It should be used from a pneumatic dropping bottle.—I am, respectfully,
SAMUEL FRY.

Proceedings of Societies.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board of Management held their monthly meeting on Wednesday, August 6th.

The minutes of the previous meeting having been read and confirmed, Mr. Bradforde (of Bath) was proposed and duly elected an ordinary member of the Association.

The offer of "Kaleidoscope" to subscribe ten shillings to a PHOTOGRAPHIC NEWS Fund for the Photographers' Benevolent

Association, with the proviso that nineteen others would do likewise (see NEWS of July 25th) called for and received the thanks of the Board. It is to be hoped that the necessary number of members will be found to support the proposer.

After some further discussion on the business of the Association, the meeting adjourned till September 3rd.

Talk in the Studio.

CORNWELL POLYTECHNIC SOCIETY.—The Annual Exhibition of the Royal Cornwall Polytechnic Exhibition will open on Tuesday, the 2nd of September. We hope that the photographic department—generally very interesting—will be as good as usual. Mr. William Brooks, of Reigate, will take part in its arrangements, and will, we have reason to believe, act as one of the judges.

DECOMPOSITION OF CHLORINE.—We recently stated that from experiments made by Mr. Norman Loekyer, there was reason to doubt that the elements were simple homogeneous bodies. Some recent experiments by Professor Meyer, of Munich, point to the conjecture that chlorine is a compound body, of which oxygen is a component part.

ALLEGED ROBBERY BY A PHOTOGRAPHER.—John Charles Lingard, 24, described as a labourer, James Harford, 31, a photographer, and Thomas Small, 30, a dealer, were indicted for stealing a watch, the property of James Earley, from his person. For the defence it was urged that it was a case of mistaken identity, and witnesses were called in order to prove an *alibi*. The jury, however, in the result, convicted the prisoners. Former convictions were proved against Harford and Lingard, who were sentenced to seven years' penal servitude, and Small was sent to prison for twelve months.

EFFECTS OF COLOURED LIGHT.—A French *savant*, M. Baudrimont, has noticed an unmistakable, but at present obscure, connection between the amount of evaporation from a given surface, and the colour of the light by which it is illuminated. Evaporation is very small under a red or a green light; it is greatest in a yellow, or in ordinary white light. This fact is, doubtless, connected with the action of certain colours on vegetation and animal development. That the different colours of the spectrum have an influence on vegetation has long been known. Plants grown under green glass soon die; under red glass they live a long time, but become pale and slender. Mr. Yung, of the University of Geneva, has placed the eggs of frogs and fishes in similar conditions, and found that violet light quickens their development, and blue, yellow, and white also, but in a lesser degree. Tadpoles, on the contrary, die sooner in coloured light than in white light.

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES.—In noticing the first part of an atlas bearing the foregoing title, *New Remedies* says:—"The method of illustration adopted resembles that of the Albert-typo, in which a photographic negative is made of a nature which adapts it to be used to print from, and the difficulty which has heretofore been met with in colouring a photographic surface is avoided. In the present instance the colouration is little more than the faintest possible wash, the prominent shadows or features of the picture being retouched with India ink and colours. Attempts have already been made to make use of photography for the delineation of skin diseases without an approach to the success which has been achieved in the present instance."

CHEMICAL COMBINATIONS.—*Appleton's Journal* contains a calculation by Berthelot, the eminent chemist, of the number of combinations which may be made of acids with certain alcohols. He says: "If you give each compound a name, and then print 100 lines on a page, and make volumes of 1,000 pages, and place a million volumes in a library, you will want 14,000 libraries to complete your catalogue."

NON-EXPLOSIVE PYROXYLINE.—Herr Schering, of Berlin, has patented, under the name of "celloidin," an unexplosive substitute for gun-cotton for making collodion. He claims that, while making an excellent preparation, it being entirely soluble in the mixture of ether and alcohol, it has the advantages over gun-cotton of neither being capable of igniting spontaneously, nor exploding when rubbed or pounded, thus being entirely safe for transportation. Its only objectionable feature is the length

of time required for solution, which, especially when very dry, far exceeds that necessary for dissolving gun-cotton. It is probably made by partial evaporation of collodion.

To Correspondents.

DRY PLATE.—If you follow instructions exactly and fail to get good results, it is impossible for us to point out the cause for such failure. The thinness of image is generally the result of over-exposure, and fog is generally produced either by the presence of light in the dark room, or injudicious use of ammonia. So far as we know, the plates you are using are the best. We do not hear such good accounts of those you enquire about at the close of your letter.

E.—You will be able to obtain the specification you require at the Patent Office, in Southampton Buildings. You must examine in the index of names for the name of Edwards, as the patentee. We do not remember the special claim of the patent, but, so far as we remember, detaching the film containing the printing surface was one important point. 2. Probably to give pliancy, and prevent a dry, brittle condition. 3. Chromo alum and tannin produce insolubility independent of the action of light.

LUNA.—The best way, we think, to obtain a thick coating of gelatine on paper will be to apply successive coats, allowing each to dry before applying another.

C. M. D.—In order to get your photographs published, you should communicate with a photographic publisher, showing examples of the work. If the pictures are attractive and likely to please the public, you will have no difficulty. The question as to who shall print them, &c., will depend upon arrangement. Probably the largest and most successful photographic publishers are Marion and Co., of 23, Soho Square. The Stereoscopic Company, of Cheapside, also undertake such publication.

A TEN YEARS' SUBSCRIBER.—Lead is an expensive material, but is generally found to be durable. Probably slate, carefully cemented, is the best material you can use. We cannot refer you to any article on the construction and arrangement of dark-rooms. Probably we shall have something to say on the subject next week. As a rule, they have to be made just as circumstances and convenience permit.

IN A FOG.—Captain Ahney described his method of eliminating fog in emulsion plates in a paper read before the Photographic Society, which was afterwards printed in our pages. The readiest reference is to his work on *Emulsions*, in which he says:—"There is also a method of eliminating fog from the dry plate when it is coated without doctoring the emulsion at all. This need not only apply to washed emulsions, but can be effected during the washing of the plates prepared by the unwashed emulsion. In addition to the elimination by the acids, &c., we can further effect it by using a solution of potassium bichromate, permanganate of potash, or peroxide of hydrogen." And further on he says:—"Plates which fog through having been exposed to light may be rendered ready for exposure by washing off any preservative they may have on them, and immersing them in a hock-coloured solution of potassium bichromate. After washing, a preservative may again be applied."

JUNIOR.—Shellac can be dissolved in alcohol by the aid of gentle heat. Methylated spirit will do perfectly as well. It will probably appear turbid at first, but if left to stand a few days an opaque deposit will settle, and the clear portion should be carefully decanted off.

QUERIST.—You will find Mr. Jarman's articles in the three issues of the PHOTOGRAPHIC NEWS preceding the present, July 11th, 18th, and 25th.

M. R. D.—Plain unbleached calico is a good and cheap material for a background screen, if you can yourself apply a coating of distemper colour. Woollen cloth is sold for the purpose, and answers well.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. MEYER'S IMPORTANT DISCOVERY, AND A POSSIBLE EXPLANATION OF THE FORMATION OF THE LATENT IMAGE—GINX'S BABY.

Meyer's Important Discovery, and a Possible Explanation of the Formation of the Latent Image.—Our readers may remember that some months ago Mr. Norman Lockyer, F.R.S., published some interesting speculations (to call them nothing more) on the disassociation of the elements. He started the theory that many of the bodies which we now look upon as elements are not elements at all. This theory was in a measure corroborated by a vast number of spectrum pictures which he had secured by the aid of photography. Mr. Lockyer's view, broadly stated, was this: that if you heated certain so-called elements to a very high degree, they gave evidence of being of a simpler nature than they were before. If you looked at an element through the prism of a spectroscope, and regarded the lines in the bands of colour, you would find that these lines, numerous at first, would become less, if a very high degree of heat were made use of. The lines not only become less, but they grow larger and brighter. Hence Mr. Lockyer considered that heat had reduced the body to a more simple form. The spectra of our brightest, and, therefore, hottest stars, contained fewer lines than the less brilliant ones, as Mr. Lockyer was able to show by his photographs of those heavenly bodies. Hence he concluded that, instead of our being in possession of many elements, there are but very few which deserve the name, hydrogen, no doubt, being one of them. This view of Mr. Lockyer's has lately assumed increased importance from the fact that a Swiss chemist is now in a position to prove that chlorine is no element; nay, more, that another friend of the photographer, iodine, is an impostor also, and has no right to the appellation it has so long usurped. We need not say that bromine—to the discovery of which we are indebted to the last president of the French Photographic Society, M. Balard—may, under these circumstances, be expected to fall also. The discovery that chlorine is no element must rank as one of the grandest of the age, certainly with Pictet's assurance that oxygen and its kindred could be liquefied. To photographers the matter will be of exceeding importance, and, as we shall presently show, it may lead to an explanation of the creation of the latent image. The discovery is due to Victor Meyer—or, perhaps, we should rather say, to MM. Victor Meyer and Carl Meyer, for these gentlemen have been conducting their experiments hand in hand. They desired to test the vapour density of chlorine at certain high temperatures, and hence they subjected it to degrees of heat varying from 620° to 1567°. At a temperature of 808° an evident splitting up of disassociation of the so-called element was apparent, and this disassociation remained constant at temperatures above. The density of the heated vapour was exactly two-thirds of what it had previously been, proving beyond a doubt that no longer chlorine, in the condition we know it, was there. M. Victor Meyer at once proceeded to examine the heated vapour further, and then found that traces of oxygen were given off. Thus we have the fact that by heating chlorine oxygen is evolved, and we may mention to our readers, what has not yet been made known in public, that at a recent investigation conducted by M. Meyer, a quantity no less than a litre of oxygen was secured by the heating of chlorine. There can, therefore, no longer be any doubt about the fact. Chlorine is no element, but, as M. Meyer chooses to call it, $M + O$, or murium and oxygen. Berzelius had the theory that chlorine was an oxygen-containing substance, and he it was who suggested the murium theory; but it has remained to M. Meyer to establish the fact. Iodine, M. Meyer tells us, behaves, so far as change of density goes, in a way similar to chlorine; but

they have not yet proceeded to extract oxygen from it, although there is little doubt that they will succeed. Bromine must necessarily follow, and then, perhaps, the explanation of the latent image, whether formed in the presence of bromide or iodide of silver, will not come so difficult. If light can act in the same way as heat, and liberate oxygen from bromine and iodine, in a photographic film the oxygen combining with the metal naturally brings about incipient reduction, and hence we get an explanation of the formation of the image. That the image was due to the conversion of a portion of the iodide into sub-iodide has long been a theory with chemists at the head of whom is Mr. Spiller, and we should think, therefore, that he would support the theory we have just expressed. If we can prove that free oxygen comes from the iodide as it does from iodine, during the sojourn of the photographic plate in the camera, the formation of the image would certainly be no longer such a mystery as it is. But in any case, M. Victor Meyer's discovery is a great one, and, as we said before, it curiously supports Mr. Lockyer's expressed opinion that many bodies we now hold to be elements are not elements at all. In the same way, it will give confidence to young chemists in proving to them that the field of research is by no means so exhausted as they have supposed. Instead of having found out everything worth finding in chemistry, we are apparently but on the threshold of that world of science. Not only have we still much to learn, but a great deal to unlearn into the bargain. There are several other elements that will be attacked, now that a whole group have been compelled to surrender, and we shall be mistaken if the step made by the brothers Meyer is not at once followed by other doughty chemists.

Ginx's Baby.—What has become of Rejlander's negatives? we were asked the other day. Now that carbon enlargements can be executed upon the most magnificent proportions, and we thus secure pictures that are snitable both by reason of their permanence and size for dining room or library, the character sketches by Rejlander should be capable of profitable reproduction. We wonder the Autotype Company or some other similar establishment has not given attention to such a series of pictures. "Is it True," "Did she," "At the Play," "Box of Lights, Sir," and the other characteristic plates, must be in existence somewhere, and they have only to be put before the public in a suitable form to command purchasers. No doubt, putting before the public is one of those things easy enough to talk about, but difficult of execution, and there cannot be a doubt that unless it is at the Annual Exhibition at Pall Mall, the outside public have little means of knowing what photographers can do and are doing. We see that the last appearance of "Ginx's Baby," Rejlander's famous picture, is on the outside of a sheet of music. There is a Ginx's baby galop or polka, or something of the sort, and on the frontispiece is a copy of the well-known photograph. The last time we saw a piracy of the picture was at the Paris International Exhibition last year. Wandering through the Belgian courts we saw the familiar features of Ginx's Baby grinning at us through a glass case. There were big babies and little babies burnt in upon porcelain, but they were all of one common stock. Rejlander, by the way, when he first sent his picture to the Pall Mall Gallery, labelled it "Mental Distress," and it was the honorary secretary of the Society who christened it Ginx's Baby in the catalogue. Rejlander did not half like the new name, and wrote demanding that it should be changed. The amendment was promised in the next edition of the catalogue, but the change was never made, and the new name stuck to the picture evermore. It was the most successful of all Rejlander's productions, and its sale throughout the kingdom reached tens of thousands; it was, indeed, the only one from which Rejlander reaped a substantial benefit, and its fame has not yet deserted Ginx's Baby, seemingly.

GERMAN CORRESPONDENCE.

BY DR. VOGEL.*

STUDY OF ANATOMY FOR PHOTOGRAPHERS—WHAT IS STYLE—ON THE VALUE OF STRONG PRINTING BATH—PHOTOGRAPHING OIL PAINTINGS—RECENT INVESTIGATIONS OF GUN-COTTON—GELATINE PLATES FOR THE PRINTING PROCESS—ELECTIC LIGHT ENGINES—AGITATION AGAINST PHOTOGRAPHY—LÆSCHER AND PETSCH'S NEW STUDIES FROM LIFE.

IF, twelve years ago, it would have been intimated to any photographer that the study of anatomy was not out of his sphere, he would simply have ridiculed the matter, although at that time anatomy had already its place on the line of studies in every academy of art; and the young painters had to study bones and muscles, not alone from models and pictures, but also from living bodies, and in the dissecting room, in which they had to take a practical part. And now Mr. Hartman, the well-known partner of the firm of Lœscher and Petsch, who, nine years ago, published the highly interesting article on the aim and scope of the retoucher, finds his lectures on the anatomy of the head not only not ridiculed, but listened to with infinite interest. Everybody who was present at his lecture was convinced that only a thorough knowledge of the bones and muscles of the head enables the retoucher to avoid those ridiculous mistakes which Mr. Hartmann points out in a very interesting example. Some knowledge of the anatomy of the head is therefore obviously of very great advantage to the thinking photographer, and I would like to suggest to reproduce the picture of the human head, with remarks, a part of which I gave in my last, by Mr. Hartmann, on page 39, in the May number of the *Photographische Mittheilungen*.

In my letter which was published in the May number, I wrote about the strong printing bath which Mr. Brandt recently recommended to use, in order to avoid some defects caused by weak baths; but some experiments lately made here did not sustain Mr. Brandt's assertions in all cases. The fact is that our paper is now salted much less than formerly, when up to three per cent. of salt was used, while now only one per cent. is considered sufficient, which makes it that a much less quantity of silver salts is required to form the chloride into chloride of silver. For this reason alone no such strong baths are necessary any more, as were formerly in order; but it appears also that some papers resist strong baths (eighty grains per ounce), a defect which can only be remedied by adding three per cent. of alcohol. Furthermore, it seems that blisters and bladders make their appearance with a strong bath just as often as with a weak one. On the other side, a strong bath can be used up to the last drop, while a weak bath is soon used up, so that it produces only very weak copies: and only through fuming with ammonia this defect can be met.

I read lately, in one of our English contemporaries, the statement that the reproductions of oil paintings are on the Continent much better than in England, and in explanation of this occurrence the assertion was made that the most and the best copies from oil paintings on the Continent are not made from the original pictures, but from copies of one colour, specially prepared for the purpose, and that not so many of such copies are made in England as abroad.

Now this assertion is erroneous. The two main establishments for photograph reproduction from modern oil paintings are, I believe, Goupil, at Paris, and the so-called "Photographische Gesellschaft," at Berlin; and both establishments photograph directly from the original paintings. Formerly, to be sure, sometimes copies were made in black chalk from the old oil paintings, and the photographs taken therefrom. Such was the practice, for example, in the celebrated gallery at Dresden.

* *The Philadelphia Photographer.*

But since the "Photographische Gesellschaft" has been granted the privilege to photograph oil paintings directly from the originals, this practice has been out of use, and I know of only one instance, that recently a one-coloured copy was made from an original painting for photographic use, and this was with Makart's "Catharina Cornaro." All other reproductions of oil paintings which were issued at Berlin were made directly from the originals, and they owe their excellence to the skill of the operators, who are schooled in this branch, and to the judicious negative retouching.

Some time ago I reported to you the experiments on photographic pyroxyline by Dr. Wolfram, and recently the well-known photographic chemist, Dr. Eder, has published an essay on the composition of pyroxyline, which disputes some of the grounds taken by Dr. Wolfram. In the first place, Dr. Eder declares the different kinds of pyroxyline to be *nitrate*, not substituted *nitro* compounds, so that pyroxyline contains nitric acid, instead of the nitrous acid (NO_2), in which assertion Dr. Eder diverges from all former views. He enumerates five different kinds of pyroxyline, of which the highest is cellulose hexanitrate ($\text{C}_{17}\text{H}_{11}\text{O}_6$ (NO_3)₆). It is insoluble in alcohol. All the others (cellulose pentanitrate to cellulose dinitrate), however, are soluble in alcohol ether, and become colloidal.

Recently Mr. Wilde placed a singular kind of gelatine dry plate in the market, which differs from the other plates in that it is destined for the positive, and not for the negative process. They are lighted in the printing-frame till the picture has appeared perfectly distinct and strong, and the picture is then simply fixed and washed, and represents then an excellent positive, free from structure and grain, which so often disturb in carbon diapositives. Such positives are very suitable for enlargements, as from them enlarged negatives are made in the camera with the colloidal process.

The electric light apparatus engrosses the attention here more and more of late, so that they are already manufactured in wholesale for laboratories, galvano-plastic, and photography. A Mr. Metzger, in Alt Breisach, now furnishes an apparatus which can be attended to by a couple of men, and producing an effect of light corresponding to three hundred candles (a common gas-burner of a gas-lamp in the streets has a strength of about four candles), for \$150. The whole machine weighs one hundred pounds.

The other day they held in Pomerania a monster pastoral camp meeting, in which the worthies indulged, as usual, in fiery and ungrammatical tirades against everything and everybody, apart from the chosen few; but an unsophisticated tiller of the soil clapped on the climax, and became at once the cynosure of a thousand admiring eyes when he thundered forth the immortal words, "The social misery, and the wicked doings of the bad Socialists are solely due to the throwing of flowers in corso-processions, the drinking of beer, and the desire of people for having their portraits taken." It has been proposed to elect this honest gentleman to be the patron of photography, and to vote him a beer-glass, a bouquet, and a head-rest as emblems of his high office.

In spite of this Quixotic crusade against photography, there appeared, of late, some excellent productions which caused deserved admiration in the public and in experts; I mean the pictures by Lœscher and Petsch, destined for the exhibition at Sydney. In contrast to the hitherto current practice to choose backgrounds of a very subdued hue, and reserving the main light for the person, Messrs. Lœscher and Petsch have taken quite bright, almost light backgrounds, from which the figure stands out dark. To be sure, the effect of some faces will be like a negro's, which would not suit exactly an American, but this happens only in exceptional cases. Lœscher and Petsch put a window decoration on such a white background, and placed

a lady in front of it, who is fairly drowned in the strong light coming from the back, without appearing dark in the least. The pictures appear altogether as if they were no photographs from life, but copies from oil paintings. An extremely bold idea it was, too, to photograph a group not in the atelier, but in the open country, right in the sunshine. It is a young lady, sitting before a wall, in the full glare of the sun, who makes funny gestures with her fingers, throwing the shades upon the wall, where they are watched with evident enjoyment by a nice little boy in a suit of black velvet. The whole idea is extremely hold, but the effects are a capital success.

As Mr. Hartmann said to me, the secret in these kinds of pictures lies in hitting the exact time of exposure; half-a-second already causes total over-exposure. It would certainly be a daring undertaking to take portraits in this way; but such pictures are best capable of showing to the public at large to what a degree of perfection photography, as an art, may aspire.

ARTISTIC RETOUCHING.

BY O. W. OSBORN.*

NEGATIVE retouching has become so firmly united with the regular photographic practice, and the superior results obtained by its use (when properly done) have won for it such a multitude of votaries, that it is almost useless for anyone to utter a word or raise a feeble voice against its use (or abuse) as practised at the present day.

To be a good retoucher, one must know something; in fact, he must know a great deal, for the proper retouching of a negative cannot be accomplished by a mere dolt or dunce whose sole aim and object is the acquisition of dollars and cents. When a man is prompted by mere mercenary motives to enter into the ranks of the great army of retouchers, and seizes a pencil and hangs away at a negative until the sound of the pencil point coming in contact with the varnished plate can be heard in all parts of the room, and after the expenditure of five minutes' artistic (?) skill, he passes the plate to the printer with the satisfied air of one who knows what he is doing, you may set that booby down as an artistic idiot of the first water. He has no business in the profession, and should be spurned by all true lovers of the art photographic. It is far better to leave a negative just as it was when fixed and varnished, rather than entrust to an incompetent person to remedy the defects.

I do not wish to be understood as opposed to genuine artistic retouching when it is confined within certain limits; on the contrary, I honestly believe there never was anything discovered which has contributed so much to the production of artistic pictures as the art of negative retouching. I speak of it as an art, for the reason that the same rules and principles of *chiaroscuro* are as equally applicable to negative retouching as to painting or engraving.

Proprietors themselves are very often to blame for the mass of poor work that is commonly turned out in the smaller cities and towns over the country. Even in the larger cities there is a great deal of retouched (?) work sent out from some of the lesser galleries that is simply a disgrace to the gallery wherein the work was done. If proprietors could be induced to believe that it is far better, in every respect, for them to employ only first-class workmen in all branches of the photographic business, they would learn in a very short time that the public would appreciate their efforts to give them good work, and consequently would be willing to pay accordingly.

But one thing must be borne in mind, and that is, that fine retouched card Rembrandts cannot be made at one dollar and fifty cents per dozen. A reasonable price must be charged, or else the quality of the work must suffer; for no man can afford to hire help, and pay fair wages for the same, without first establishing a list of prices which will allow him a liberal margin, and insisting upon at least a partial payment at the time of making the sitting.

* *St. Louis Practical Photographer.*

Almost everyone who retouches negatives has his own particular method of working, and in proportion as that method is good or bad, so will the quality of the work produced by it be good or bad. Some raise great objections to the rather old method of grinding the varnished surface with cuttle-fish, and not without some good reasons. If the material used for removing the glossy surface of the varnish be of too coarse a nature, or the varnish itself is too weak, thereby giving a very tender film, it is probable some very serious damages would result from grinding the surface; but if the material is fine and the varnish of good body, I can see no reason why any damage should ensue from its use. Powdered pumice stone is used by many and pronounced very good. A pinch of bicarbonate of soda dropped upon a varnished surface and rubbed in a circular motion with the ball of the finger will generally remove the gloss, if the negative has not been varnished too long, and leaves a magnificent surface upon which any amount of work may be done. If only the face is to be worked, it is better to grind the negative; but if much work is required all over the face, hair, and drapery, I would recommend that the negative be varnished with some good varnish, and, after it is dry, to again flow the plate with Hance's ground glass substitute. A lead pencil takes finely upon such a surface, and after all the work necessary has been performed, the retouching may be covered by another coating of the regular varnish. This second coating is a great advantage, inasmuch as it separates the retouching from the paper, thus considerably softening the work, producing a sort of mezzotint effect which adds considerably to the beauty of the finished print.

The best method I have ever found to remove spots, freckles, pin-holes, &c., is to take a medium hard pencil and sharpen it with a knife and a piece of sand-paper, making it very sharp, and with this touch out all imperfections. If an attempt is made to remove pin-holes and freckles with India ink, the chances are about ten to one in favour of your producing a first-class failure; for when a transparent spot is touched with ink, you will observe in the proof a little round white ring with a black centre.

In all my experience—and it has extended over a dozen or more years—I have used a great many new retouching pencils, but I find, after all, Faber's graded pencils are the best it has ever been my fortune to use.

In commencing work, begin by softening some of the deepest wrinkles, without, however, entirely removing the same, and touching out some of the largest freckles. Remove the greater blemishes first, which will cause the plate to present a smoother appearance by transmitted light, and give you a chance to judge of the general effect. The province of the retoucher should be to remove the defects and exaggerations, and, I may say, falsifications, to which the camera is prone. But some are bent on producing the beautiful stippled effects so often seen in the work done in the finest metropolitan studios, without stopping to think that such work is done by real first-class workmen who, perhaps, have had many years' experience in the finest galleries in the country. Perhaps their efforts were crude at first, but by constant practice and untiring efforts they have acquired that skill and dexterity of touch which characterizes the master workman, and distinguishes him from those who have drifted into the retoucher's chair simply because they have failed in everything else. How mortifying it sometimes is to a good operator, who, having made a fine negative and given it to the retoucher, gazes with astonishment upon the proof, and wonders whether retouching is or is not a fine art. Instead of the retoucher confining himself to the removal of those little imperfections which are always met with in some shape or other, he attempts to produce something grand (just because the operator did a good job) and has worked and negged the life and character all out of what was, in the beginning, a really first-rate negative, until there is nothing left for the operator to do but make another negative and have the retoucher improve (?) it in the same manner as he did the first one. How often do we find pictures which, although exhibiting marks of

superior excellence, are at the same time so worked to death in the face, that what was once a finely modelled and artistically lighted picture, is now nothing but a miserable apology—with all the delicate shadows removed, and the face as flat as a board.

First make a fine negative, and then remedy the defects by retouching. While a little judicious work on a good negative will sometimes greatly improve it, yet no amount of retouching will improve a really bad or under-toned negative. As a skilled designer would never dream of passing his drawing over to a botch engraver, to be spoiled and caricatured, neither should the operator, who values his reputation as an artist, ever entrust his work to be finished by one of those modern Raphaels (!) who know no more of the true principles of art than a cannibal does of the kingdom of heaven.

For many years I have practised a little dodge which saves a good deal of work, and produces results which are very nice; in fact many consider such results as embodying a little more than ordinary merit. It is this: coat a negative on the glass side with a mixture composed of equal parts of good negative varnish and Hance's ground glass substitute, and after it is dry, which will be in from five to fifteen minutes, take a soft lead pencil and strengthen the high lights, if found necessary, by rubbing a small spot on the varnish where the strongest light should be; make this spot very intense, but do not make it much larger than a pin's head for a card negative. A line may be drawn down over the nose, but this had better not be attempted unless great care is exercised, as a little movement one way or the other will be productive of bad results. Large masses of shadow on the face can be considerably softened by this method, and made to print as much lighter as may be thought necessary. In fact, when a weak, flat copy is treated in this manner, and the negative is held square with the sun during printing, it will make the eyes of the uninitiated stand open like the cellar doors of a country town, to behold the difference between the prints. Retouching on the glass side of a negative is an old dodge, and, I may say, one of the best I ever saw; for, even if the work is put on a little coarse, the separation from the paper during printing will give to the high lights so treated a peculiar softness and beauty which are not to be despised. Negatives from life which are too weak to yield a brilliant print can be treated after the same manner above indicated, and made to yield prints which have a peculiar character of their own, and, if well done, will entitle such work to rank first in the grade of merit.

The retouching frame is too well known to require ad notice here. Suffice it to say that I have found a sheet of white paper or cardboard to be an improvement over the mirror commonly in use, inasmuch as it is pleasanter to the eye, and does not produce that disagreeable glare which is sure to result when a mirror is used.

It must be remembered that there is something more required to make a good retoucher than the simple pencil and magnifying glass. If such was not the case, then one retoucher would be as good as another, provided his tools were as good. But, unfortunately for many, the retoucher must, or at least should, be able to commence where the operator left off, and continue the work by means of the pencil which it was almost impossible to do with the camera or chemicals. He should be able to grasp the photographer's idea and carry it forward to its successful completion. Unless the workman can do this in a greater or less degree, he had better abandon the business to some one else, as a poor retoucher is a shade worse than none.

Every man who understands the first elementary principle of art, knows that if we have a brilliant light in a picture, it is absolutely necessary to support that high light with a mass of shadow, in order to preserve harmony and give character and breadth of effect.

The more artistic ability a retoucher possesses, the more perfect will be his productions, and *vice versa*, for I maintain that the same rules and principles of light and shade govern

the one as much as the other, and unless a person has some talent in that direction, he or she had better surrender the business, and pursue some avocation for which they possess more and better qualifications.

PURIFYING AND SOFTENING WATER.

A PROCESS for completely removing the hardness of water, and rendering it equal to distilled water in softness, has been recently patented by Mr. A. Ashby, of Grantham. The process is especially useful for manufacturing and industrial purposes, but may also be employed for removing the whole or part of the hardness from water used for drinking or domestic purposes. After the temporary hardness, which is due to the presence of bicarbonates of lime and magnesia, and salts of iron, has been removed from the water by the addition of lime or lime water (Clark's process), by boiling, or by any other known method, the patentee adds, for the purpose of removing the permanent hardness which is due to the presence of soluble salts of lime, magnesia, and iron, other than those which cause the temporary hardness, a sufficient quantity of a solution of carbonate or bicarbonate of soda or potash, or of any other soluble carbonate or bicarbonate which will decompose and effect the precipitation in an insoluble form of the substances which produce the permanent hardness, either with or without the aid of heat, which may be applied either by means of a fire, or by passing steam through coils of pipes placed in the water to be softened, or by blowing steam directly into the latter. The waste or exhaust steam from a steam-engine may be employed as an economical source of heat. Or he removes the magnesia, which may wholly or partially cause the permanent hardness, by the addition of an excess of lime during the removal of the temporary hardness, whereby the water is rendered alkaline, and the magnesia is precipitated in an insoluble form, the excess of lime being subsequently removed by the addition of a sufficient quantity of carbonate, or bicarbonate of soda, or potash, or of any other soluble carbonate or bicarbonate, and when necessary by the addition of some free carbonic acid gas after the addition of the soluble carbonate, whereby any caustic alkali which may have been formed is converted into a carbonate. The patentee prefers to have a separate mixing tank, in which the solution of carbonate or bicarbonate may be added after the lime water has been previously added to the hard water in another mixing tank, and to have the second mixing tank of larger dimensions than the first. Where there is steam or other power, stirring gear should be placed in each tank.

In the process described the free and half-combined carbonic acid gas is first removed, so that the subsequent removal of the permanent hardness is rendered both practicable and easy. The process may be used in conjunction with Clark's process, but it is preferred to use it in conjunction with the Potter-Clark process, which removes the temporary hardness from water. The patentee says that after water has been treated by this process, it is devoid of all hardness, so that it is equal to distilled water for washing and manufacturing purposes. When determining the proper proportion of soluble carbonate or bicarbonate to be used, proceed as follows:—After a sufficient quantity of lime or lime water has been added to combine with the free and half-combined carbonic acid, or, if required, sufficient also to remove magnesia in an insoluble form, take (say) a quarter or half-litre of the water, and drop into it from a graduated glass measure (*e.g.*, a burette divided into cubic centimetres and parts of cubic centimetres) some solution of soluble carbonate or bicarbonate of one per cent. strength, or of any other strength that may be found to be most convenient, and preferably some of the same solution that is going to be used in the process of softening, and then raise the water to as nearly as can be the same temperature as that to which it will be subjected during the process. In order to ascertain when just a sufficient quantity of the solution has been added, the patentee uses turmeric or reddened litmus paper, so as to avoid having an alkaline reaction in the water, or he adds a little solution

of calcic chloride to some of the water after it has been filtered into a glass vessel, when no turbidity ought to be produced in the water; or some of the filtered water is added to a few drops of a solution of mercurous nitrate or of mercuric nitrate placed in a white basin, when no change of colour ought to take place; or any other convenient chemical reaction may be employed as an indicator. If a slight degree of alkalinity in the softened water is of no consequence, so much care need not be bestowed on this point. Should it be desired to remove only a portion of the permanent hardness, a smaller quantity of the solution of carbonate than is indicated above may be added, and the resulting hardness of the partially softened water may then be ascertained by the standard solution of soap in ordinary use. Having now determined the relative proportions of the water which is to be softened, and of the solution of soluble carbonate or bicarbonate which must be used in order to effect the desired amount of softening, the size of the orifices of the rectangular valves or openings through which either flows into the second mixing tank must be adjusted in the like proportions. For example, if 1,000 measures (say one litre) of the water required 10 measures (say 10 cubic centimetres) of the solution of carbonate, the two orifices must have the relative areas of 1,000 and 10. This adjustment is effected by having a slide plate fitting into one or both of the rectangular openings, which is moved by a screw so as to increase or diminish the size of the openings. A graduated scale is placed either by the side of the sliding plate or on a circular plate at the end of the screw, which is used for turning it, or in both positions combined. In this manner the relative areas of the openings can be readily and accurately adjusted; but care must be taken that the fluid issuing from each opening has as nearly as possible the same head of pressure; a float can be arranged so as to cut off the orifices in equal proportions as the mixing tank becomes filled.—*English Mechanic.*

DECOMPOSITION OF THE "ELEMENT" CHLORINE.

It will be within the memory of many readers that some recent experiments of Mr. Lockyer pointed to the conjecture that many of the so-called simple elements were compound bodies. Still more recently professor Meyer, a Swiss chemist, has arrived at some confirmatory results, and has obtained a litre of oxygen from pure chlorine. The *Times* has an interesting notice of the matter, and remarks that "chemists and physicists now almost universally entertain the theory that all bodies, whether gaseous, liquid, or solid, consist of extremely minute particles or molecules. Each molecule consists of a definite quantity of matter, which is exactly the same for all molecules of the same substance. The molecules of most substances, however, are themselves compounds, and consist of atoms which, as the name implies, are held to be indivisible; but whereas the molecules of what are ordinarily termed compound bodies contain dissimilar atoms, the molecules of the so-called elements are supposed to be composed of similar atoms. For example, in a molecule of water two atoms of hydrogen are combined with a single atom of oxygen, but a molecule of hydrogen consists of two atoms of hydrogen, and a molecule of oxygen of two atoms of oxygen. The molecules of the elements do not always contain two atoms, however; the molecule of mercury, consisting of a single atom, and that of phosphorus of no less than four.

"To determine the number of atoms which compose the molecule of any given substance is one of the most important operations the chemist is called upon to perform. The method in use is based on the theory that equal volumes of all substances in the state of gas, if at the same temperature and pressure, contain equal numbers of molecules; so that, whatever the actual number of molecules in a given volume of gas, if the weight of the given volume of gas be ascertained and compared with the weight of the same volume of another gas under precisely the same conditions of temperature and pressure, numbers are obtained which represent the relative weights of the molecules of the two gases in question. These

numbers are always the same whatever the temperature and pressure at which the comparison is made, provided that no decomposition of the molecules of either of the substances occurs. The determination in question is known as the determination of the gaseous or vapour density of a substance.

"Either air or hydrogen is taken as the standard of comparison, the latter being the more convenient, as it is universally adopted as the standard to which the atomic weights of the elements are referred, the atomic weight of an element being a number which represents the weight of its atom supposing that of the hydrogen atom to be 1. Using the hydrogen standard, if we say, for example, that the density of oxygen is 16, we mean simply that a given volume of oxygen weighs 16 times as much as an equal volume of hydrogen.

"Certain considerations which need not here be entered into lead us to suppose that the molecule of hydrogen consists, as we have said, of two atoms, so that if the weight of the hydrogen atom be unity, the weight of its molecule is twice as great; in other words, 1 being the atomic weight of hydrogen, 2 is the molecular weight of hydrogen. Hence if we determine the density of any substance in the state of gas relatively to that of hydrogen, we have merely to double the number representing its density in order to obtain the weight of its molecule as compared with that of the hydrogen molecule; and dividing the number representing the molecular weight of an element by its atomic weight, we obtain a quotient which expresses the number of atoms in the molecule of the particular element. Thus, the density of ordinary oxygen being 16, its molecular weight is twice 16, or 32; and, therefore, since 16 is the atomic weight of oxygen, the molecule of oxygen consists of two atoms. But if we take oxygen in the state of ozone, we find that its density is higher than that of ordinary oxygen—viz., 24; the ozone molecule is therefore twice 24 times as heavy as the hydrogen molecule; and since the quotient of 48 divided by 16 is 3, we conclude that it consists of three atoms, the molecule of ordinary oxygen consisting of only two atoms. When moderately heated, ozone is entirely converted into ordinary oxygen, and the density diminishes from 24 to 16, or to two-thirds of its value.

Some few months ago Professor Victor Meyer, of Zurich, devised a new, most ingenious, and expeditious method of determining gaseous or vapour densities, and as it enabled him to work at high temperatures with far greater facility than any of the methods previously known, he was led, in conjunction with Herr C. Meyer, to make experiments with a variety of substances, and among others with the "element" chlorine. The results they obtained at temperatures not much exceeding 600 degrees centigrade were in accordance with previous observations made at lower temperatures, being such as to indicate that the molecules of chlorine, like those of hydrogen and oxygen, each consisted of two atoms. But on extending their observations to higher temperatures they noticed that the density diminished until at about 1,200 degrees it was only two-thirds as great as at 600 degrees and below. No further alteration, however, occurred, on heating to nearly 1,600 degrees. The change in density being precisely similar to that observed on heating ozone, it would appear possible that a similar kind of alteration in the composition of the molecules of chlorine had occurred—that is to say, that the chlorine molecules are composed of the same kind of atoms, but in different numbers at low and at high temperatures. There are, however, a variety of considerations opposed to such a conclusion, and it would appear more probable that chlorine is not an element, as has hitherto been supposed, but a compound of dissimilar atoms. It is stated that the Messrs. Meyer have actually succeeded in proving this and that oxygen is one of the components of chlorine; but no particulars of their experiments have as yet come to hand.

"Such a discovery would be the first approach to a substantiation of Mr. Lockyer's views of the non-elementary character of the so-called elements to which we had occasion to refer at length some few months ago, and which were chiefly based on observations of the spectra of the metallic elements taken in conjunction with solar and stellar phenomena."

COPYRIGHT IN PHOTOGRAPHS.

As our readers are aware, a Royal Commission was appointed to consider the condition of copyright in this country. Nothing could well be more unsatisfactory than the law of copyright as it stands. Doubts have been expressed as to whether there was any protection to copyright at common law, and the whole of the statute law is fragmentary and incomplete, being contained in nearly a score of different Acts, mostly cumbrous, complicated, and uncertain in their interpretation. A Bill has been recently introduced into Parliament by Lord John Manners for the purpose of consolidating and amending the law of copyright, both in works of literature and art. Such a Bill is necessarily a very elaborate document; but it is, so far as we have at present mastered its provisions, as well-considered, just, and free from complications as the circumstances seem to permit. The provisions for copyright in books seem to meet many difficulties which have been felt unsatisfactory in the existing law; but with that portion of the Bill our readers are not especially concerned.

It is with copyright in works of fine art, especially in photographs, that we are definitely concerned here. The clauses especially devoted to copyright in photographs are free from the cumbrousness and uncertainty which characterized the provisions of the Fine Art Copyright Act. The general provisions in relation to photographs resemble those applying to paintings, but are made specific by definite provisions where the varying conditions of the respective cases demand special arrangements. Copyright accrues to the author of any original painting or photograph, whether the author is a British subject or not; and the law is to apply throughout Her Majesty's dominions at home and abroad.

The copyright in a photograph is to endure for thirty years from the date of publication. Any person who, without the consent of the owner of the copyright, shall copy the picture, or any material part thereof, or shall import, sell, publish, exhibit for sale, or have in his possession for sale or exhibition, shall be held to infringe the law, and be liable for penalties. Persons infringing copyright as protected by the proposed Act will be liable to a fine not exceeding ten pounds, and double the full price at which such paintings, photographs, or negatives have been sold or offered for sale. Such penalties to be paid to the person aggrieved.

An important point about which doubt has existed is here definitely provided for: the copyright in a photograph shall belong to the proprietor of the negative from which the photograph is printed. This definitely protects the photographer. By a succeeding clause, however, sitter in portraiture is equally protected, as the clause en-

acts that "where the photograph has been made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit any copy of the photograph without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any copy of the photograph, and, if the copyright is infringed, of taking proceedings with respect to the infringement, as if he were the proprietor of the copyright. This clause, it will be seen, defines strictly the rights of photographer and sitter. A photographer may not, without consent, exhibit or sell portraits of sitters, neither may a sitter produce or obtain copies of his portrait, as the copyright rests in the possessor of the original negative.

There are provisions for registration, and for colonial and international copyright, and provisions for fraudulently affixing names, or altering a picture, &c. Altogether the provisions of the new Bill are clearer, fuller, and more satisfactory than those of the existing Act, and should they pass into law will be much more satisfactory to all concerned than anything which has hitherto prevailed.

FRACAS IN A STUDIO.

WE read with regret, in a police report, some details of a painful scene in Mr. Faulkner's studio in Baker Street, from which it would seem that a gentleman who was disappointed with the portrait of an old lady and another one of a child emphasized his disapproval in a manner which led, according to Mr. Faulkner's statement, to a serious personal encounter. The customer, it appears, characterized the work as artistically bad, and the transaction as a swindle, demanding the return of his money, which was very naturally refused.

A newspaper report describes the affair as a "Desperate Fight in a Baker Street Photographic Studio," and says:—

"On Tuesday, at the Marylebone Police Court, Mr. Bertram Fulke Hartshorne, of 11, Neville Terrace, Onslow Gardens, was summoned for assaulting and beating Robert Faulkner, photographer, at 21, Baker Street, on July 12th. There was also a cross summons against Mr. Faulkner for assaulting and beating Mr. Hartshorne, at the same time and place.

"Both parties appeared by counsel. The facts of the case having been shortly stated in the first case, Robert Faulkner, the complainant, said that previously to the 12th July he had taken photographs of the defendant's mother and child. On the 12th, the defendant, accompanied by his mother, wife, and child, came into the drawing-room of the studio, and complained in very unreasonable language of the photograph. His manner was very insulting. He had paid witness £2 2s. Witness said the photographs were as good as could be expected, the lady being very old, and the child having been fidgetty. Witness told him he had another negative, but as the defendant's manner was so insulting, he left him, and the defendant left with the other members of the party. The defendant soon afterwards came up to him in the gallery, and said, 'Am I to understand from you that you refuse to take my photograph again?' Witness said he did refuse. The defendant asked for his money back again, but witness said he should not give it back. The defendant then said he would publish this matter amongst all his friends, and called witness a swindler. Witness went towards him, when the defendant shortened his umbrella, holding it in the middle, and aimed a blow at him. Witness rushed in to the defendant, when he felt a blow from the umbrella. He struck out in self-protection, and they both fell to the ground. Several persons then came up, and witness complained to the defendant as to the conduct of which he had been guilty.

"Cross-examined: He walked quickly across the room

to ask the defendant why he had called him a swindler. He dodged the first blow of the defendant. He saw the defendant had a black eye after the affair, and it was natural to suppose it was from the blow witness gave him with his fist. He saw that if he did not rush in at the defendant he would have had a most murderous blow that might have been very dangerous.

"Mr. de Rutzen asked if this was not essentially a case that ought to be settled. If a dozen more witnesses were called they would not alter the facts. Everything was now known. There seemed to have been heat on both sides.

"The learned counsel conferred together, but could not agree, the counsel for the complainant stating that certain terms had been used towards the latter, which must be withdrawn.

"The objectionable words not being withdrawn, the case proceeded. The parties changed places for a time, and the second summons was called on.

"Mr. Hartshorne stated that on the day mentioned he went to the shop of the defendant Faulkner about the photograph, and pointed that it was not a good one. It was not artistically good, and the defendant had taken witness's mother differently to the order, which was for a three-quarter face. The defendant treated him in a very offhand manner, and said witness did not understand photographs. Defendant then walked away, and Miss Scott, the assistant, said that he could have another photograph taken on payment of half-a-guinea, or on an order of extra copies being given. He took the ladies away, and then went up to the defendant to ask him if it were correct that he declined to return the two guineas, or to take another photograph. Defendant said it was correct, and afterwards said he was no gentleman, and witness said he had been swindled. Immediately on his saying this, the defendant flew at him and caught hold of his shirt, and witness, who was holding his umbrella in the middle, hit him on the shoulder to ward him off. Defendant then struck him in the eye, and it bled very much, and was afterwards closed up. Witness and defendant closed together and fell to the ground, and they were afterwards separated. He left the place and went home, and he was confined there for some days from the effects of the blow, and had to be seen by a doctor.

"Cross-examined: He did not say the defendant was a swindler. He did not use the umbrella until the defendant had seized him and said, 'You call me a swindler?'

"Other evidence was given on the two summonses, it being shown that Mr. Faulkner's assistant, Miss Scott, was thrown to the ground in the struggle between the parties.

"Mr. De Rutzen observed that Mr. Hartshorne had a perfect right to go to Mr. Faulkner's shop and complain about the photographs, but it seemed to have led to unpleasant remarks, and then Faulkner took upon himself to call the other 'no gentleman,' which was not a pleasant thing to say. Hartshorne said he had been swindled, and then each thought the other was going to strike him, and the assaults were committed. He should dismiss both summonses, and he thought both of the parties should apologise to Miss Scott for having thrown her to the ground."

The magistrate appears to have been puzzled by the conflicting evidence, and, regarding both parties as to blame, dismissed both summonses. It scarcely seems to be a legitimate conclusion that because the portraits of an old woman and a baby were not satisfactory—a most common and natural circumstance—a customer should be at liberty to proceed to a breach of the peace, or to use language which would lead to a breach of the peace. We know nothing of the character of the pictures, but we know that, artistically, Mr. Faulkner does not often fail. The ease and the decision here lead to nothing, and establish no precedent.

FRENCH CORRESPONDENCE.

OBSERVATIONS ON THE CONDITION OF THE ART OF PHOTOGRAPHY IN FRANCE.

If we desire to be really useful we must never hesitate to speak the truth. It is in this spirit that I feel compelled to declare frankly, and without fear of contradiction, that France, the beautiful country to which photography owes its birth, has allowed itself to be outstripped by other nations in respect of its appreciation of the value of what is *par excellence* a popular art. Photography, though it does not depend on the creative powers of those who devote themselves to it—and this is the reason why it is so often denied the right to be classed among the fine arts—exacts constant and conscientious practice; it requires special aptitude and close attention to the continua, wants of the professional public; and, as a consequence, its followers must march in the van of progress.

With a few rare exceptions, I fear that French photographers do not comply with these conditions. They are very slow in appreciating the value of technical improvements; they are with great difficulty induced to quit the beaten paths of routine, short of being absolutely forced to do so. Unlike those who are imbued with the noble desire of attaining the honours of a distinguished position, they never seem to have the slightest ambition to rise above the crowd. The majority of them do not seek to teach themselves; they read very little, and often systematically ignore every new process, because to adopt it would disturb their accustomed habits. When a new discovery, which might be of great advantage to them in their work, is mentioned in their hearing, they look as if it had dropped from the skies, and that, though the said discovery may be known all the world over, and perhaps has been the cause of success and fortune to a more intelligent rival.

I do not think I am at all overrunning the bounds of probability in asserting that there are few photographers—and it is especially in Paris itself that I have had occasion to observe what many will think almost incredible—who know anything of the chemical products that they work with, beyond the name marked on the label of the bottle, and the proper time to use them. They are completely ignorant of the scientific properties of those products, and I feel persuaded that there are not ten in a thousand of all the photographers in France who are capable of making a chemical analysis.

Photography seems to be treated like politics or geography; it is dabbled in without much thought given to it, and then its professors think themselves strong in it. At the present moment the photographs which are the greatest favourites with the public owe their attractiveness to the excellence of the retouching. The productions of the best photographic houses in France absolutely depend on the retoucher, for an untouched negative, or a portrait that has not been worked upon with the pencil, would be as impossible a phenomenon as a ballet dancer without legs. And yet it is quite impossible for a portrait painter to produce, by copying a photograph alone, a portrait which should possess any resemblance to the original. Delicacies of colour have disappeared, light and shade are altered, lines are finished inaccurately and unskilfully, the expression, the feeling, all exist no longer! To a customer who complains of the want of likeness the photographer replies stiffly that there cannot possibly be a mistake, as he invents nothing; but he forgets all the time the retoucher, who works without seeing the original, and has had the impertinence to improve the truth of the sun's rays, instead of confining himself to correcting the defects due to the imperfections of the process.

And yet, notwithstanding the constant complaints of artists at the incompetence of retouchers, no school for instruction in retouching has been established in France. Photographers are satisfied to take the first assistant that

offers—often a young lady without the slightest knowledge of drawing—to execute the delicate work of working-up their negatives or their prints.

It is true there does not exist in the country where Daguerre was born a public lecturer on photography, and we have, therefore, no right to complain that instruction is not given in the art of retouching; we can only look for the aid when we have established the means. But this only goes abundantly to prove what I asserted at starting, that France does not hold—as she ought to hold—the first place in photography; and what I mean to say is, that if this fact be recognized—if it be properly and unostentatiously deplored—there will be some hope that she may rise, by right of birth and by right of conquest, from this inferior position. By proclaiming the truth to her, I may, I trust, be acknowledged to be acting for her advantage.

This condition of inferiority which she now occupies has struck with great force all those who are interested in photographic progress, especially since the use of dry emulsions has become everywhere so very prevalent. In France alone have the processes depending on these emulsions been met with coolness. Here, the advantages they offer are still subjects of discussion, and their value and importance are discredited; there is even—though I can scarcely bring myself to confess it—serious hostility manifested against them. It is only right to acknowledge that the photographic societies and special journals do their best to get rid of this feeling, and to cause the processes in question to take root among us, but they do not make many converts; and though there are certain specialists who by their works and their researches cause a belief to exist that there is in this country a movement in favour of what I call the “new films,” it must in truth be confessed that this movement has not yet, unfortunately, spread to the photographic studios.

It may well be asked, How is an antagonism of this description maintained? We cannot admit that it is due to the fact of these new processes having been imported from abroad; however true it may be that articles of foreign invention or manufacture take a long time in making their way in France—often because the inventors or manufacturers take no trouble to make them known—there is no doubt that Frenchmen never show themselves exclusive in this respect, and, in the spirit of every intelligent people, are ready to accept improvements which have not taken their rise among themselves, without asking what is their nationality.

There is, in fact, no means of explaining the hostility that I have just mentioned as maintaining itself here in every branch of the profession except among those who are amateurs, tourists, or members of scientific societies. Professional photographers are in the habit of complaining of the importance which is attributed to the use of dry plates, and are courageous enough to ask seriously whether the continuous improvements which are from day to day introduced into photographic processes may not have a dangerous aspect for the commercial practice of photography. If I had not heard them in several quarters simultaneously, I should hardly venture to make myself the echo of such inanities; I have even heard these improvements described as threatening to destroy the profession.

Was the profession ruined when the negative processes overthrew the old positive processes of Niepce and Daguerre? Have horses been done away with since railways came into existence? Are there no longer spinners and weavers now that mules and power-looms have been introduced? One has only to observe the streets of a manufacturing town when the hands leave work for the day, to receive an authoritative answer to the question.

The French photographer is thoroughly in the wrong when he listens to the sullen voice of prejudice, and shows

such an indisposition to accept an improvement which cannot fail to open up a new era of prosperity for his art. He must be induced to follow in the forward march of other nations; it is a law which he must obey, or, as sure as fate, he will be trampled down. There is a kind of feeling of decay which seems to be prevailing among us, and great fears are entertained as to the consequences it may entail; this spirit we especially note, to our grief, at the meetings of our societies and at our exhibitions. Each succeeding meeting has a less number of persons to take part in it; each exhibition shows fewer and fewer exhibitors. The Exhibition of Science Applied to Industry has now been open for more than a month, and the number of exhibitors in the photographic section may be counted on the fingers—and that, in a city like Paris!

This result is really disheartening. It is not merely the opinion of a pessimist which, in the face of facts like these, maintains that France will soon lose the position in the photographic world she has so gloriously maintained, if she do not watch well over her future.

K. VERSNAEYEN.

ON THE PERMANENCE OF PHOTOGRAPHIC PICTURES.

BY DR. JULIUS SCHNAUSS.*

FORMERLY, when the art of photography was practised exclusively in the service of the general public, and more especially for taking portraits, attention was soon and frequently drawn to the instability of photographic productions, particularly of those on paper. This defect was an unpleasant one for the owner; but still it was not of so much importance as now-a-days, when photography is employed as an aid to science in obtaining reproductions which may be of inestimable value to posterity. I need only mention astronomical photographs, and those of rare manuscripts and prints, of the pictures of plants which seldom come into bloom, and of a thousand other infrequently occurring natural phenomena. The fading of a photograph of this kind may under certain circumstances occasion an irreparable loss. We possess at the present day three complete different methods for the reproduction of prints for photographic negatives:—1. The original silver printing, as it is called; 2. The pigment or carbon printing; 3. Printing in the press by means of fatty or printer's ink.

Silver Printing.—The foundation of this process is silver chloride, of which a thin film is produced in and on the paper by means of a double decomposition of some chlorine compound and of silver nitrate; the action of the latter substance must take place after that of the former, so that an excess of silver nitrate remains always in the paper, for silver chloride alone would render the prints grey and monotonous. At first this kind of copying paper was prepared by floating a sheet of plain paper on a solution of chloride of sodium or ammonium, and, after drying it, floating it again on one of silver nitrate; after drying a second time, the paper could be employed at once by exposing it under a glass or paper negative. Prints produced by this method, however, never possessed the sharpness of the original negative; it was, therefore, found necessary to give the paper a shining surface not liable to be injured by the various baths to which it was submitted. For this purpose the albumen of eggs proved itself to be specially adapted, and in consequence the manufacture of albumenized paper was developed to such an extent that the price of eggs rose considerably in the market. Persons unacquainted with the subject can form no idea of the enormous quantities of raw materials annually consumed by photographic laboratories in Germany alone. The same influence was observed in the rise of the price of silver, until, fortunately for photographers, a gold standard was

* *Photographisches Wochenblatt.*

established in the currency of the German empire, and in consequence the most important of all the chemicals used in photography—silver nitrate—became much cheaper.

The albumenized paper contained the requisite amount of an alkaline chloride, so that the operator can put it at once to float on the silver bath, after which it is ready for use. From the fact of albumen also forming with silver an insoluble compound, sensitive to light, a further cause of the rapid deterioration of these photographs arises, for in the so-called fixing process, which silver chloride pictures have to undergo in order to remove the salt which has not been acted on by light, and thus to render the pictures insensitive under further exposure, my experiments prove that the albuminate of silver is not simultaneously decomposed. It is also a fact, of which anyone can convince himself by inspecting the first best photographer's show-case that is exposed occasionally to strong sunlight, that albumenized pictures gradually acquire a reddish-yellow tint over the whole surface.

To another cause is due the fading of photographs on paper in general, especially of those which have been kept in a damp place; this defect is of still greater importance than the one previously mentioned, as it affects also those pictures which are kept in the dark. This fading is, more accurately speaking, a turning yellow of the deep brown or black tones of a finished chloride of silver photograph, and is caused, according to the results of careful investigation, by the formation of an extremely thin film of silver sulphide. It might be supposed that the sulphur of this compound is, in the case of albumenized prints, at least partially derived from the albumen, but in reality it is given off in large quantities by the sodium hyposulphite (or, as it is now-a-days designated, "thiosulphate") which is used for fixing the image, and for which, unfortunately, up to the present, no substitute perfectly free from sulphur has been found. During the operation of fixing, sodium chloride and silver hyposulphite are first formed from the silver chloride and the sodium hyposulphite the silver hyposulphite, by taking two more atoms from the sodium hyposulphite, forms a double salt which is soluble in an excess of the sodium salt. Silver hyposulphite alone is decomposed when deposited, and, as is well known, forms silver sulphide. A similar change, accompanied by the production of free sulphur, takes place in the course of time in the substance of the paper; this sulphur, in a nascent state, attacks the silver of the photograph, unless the greatest care has been taken in the manipulation to remove by washing every trace of the double salt of sodium and silver. Fortunately, there are various means of checking the entire absence of the hyposulphurous salts in the last wash water, but the use of them in practice is limited, more especially as this most important testing operation is generally to be watched by mere assistants to photographers.

Pigment or Carbon Printing.—For the reproduction of photographs, therefore, possessing some guarantee of permanence, it became necessary to try other methods not depending on the use of such unstable salts. A method of this kind has lately been invented, as is known, under the name of pigment or carbon printing, but experience has also shown in this case the inexpediency of prematurely cherishing illusions. The foundation of the pigment process is gelatine sensitized with potassium bichromate, and tinted with some colouring material. Doubts may at first be entertained of the permanence of these carbon prints, seeing that they depend on the presence of such an easily decomposable substance as gelatine; but the fact remains that during the developing of the image this gelatine is for the most part removed. That portion of the gelatine which remains on the paper has been completely altered in its chemical properties by the action of the chromium compounds under the influence of light, and has become nearly perfectly insoluble in water. As an extra precaution to render them completely

resistant, the prints are passed through a solution of alum. No fear need, therefore, be entertained of the gelatine as a cause of the picture's spoiling; but, on the other hand, there is much more reason to suspect the colouring material employed, to which really the picture itself is due. Pure carbon, in a state of finest subdivision, is a thoroughly permanent pigment, and should always be chosen for prints of special value. For objects to be rendered artistically, however, pure black is not a pleasing colour, and the manufacturers of pigment paper are therefore in the habit of adding some carmine or aniline colouring material in order to produce a warmer and more agreeable tint. Experience, however, proves that the permanence of the picture suffers by the addition, for these colours are liable to change under exposure to light. When we also consider that, in the hands of workmen who are not strictly conscientious, the operations of developing and washing are apt to be scamped, and that the chromium salts in consequence are not always completely removed, it is easy to see that the fading of carbon prints may even be expected. Occasionally, too, the gelatine picture peels off partially or completely from its paper support when the latter has not been very carefully prepared.

Printing in Fatty Ink.—The only process which offers a complete guarantee for the permanence of the pictures produced by means of it is the one approved by an experience of centuries—the printing in printers' or fatty ink—a substance which will last longer than the paper to which it is applied. Recent discoveries enable us from any negative to obtain a positive print on paper in fatty ink, and that with the same rapidity as is secured by the steam press in the case of ordinary type printing, it being only necessary to use greater care in rolling up. In selecting the particular method for obtaining a print, special regard must be paid to the nature of the object that is to be reproduced—whether, that is, it contains half-tones, or whether the shading can be given by lines and points, as is the case in copper plates, wood-cuts, &c. In the latter case photo-lithography and photo-zincography are the cheapest methods; but when half-tones have to be rendered, collotype must be used. Generally, we may say that collotype printing is the most important of all the methods of this kind of photographic printing. From even a good collotype plate one thousand prints can easily be taken, and these can be sold at a very cheap rate when pressed on dull writing or thin cartridge paper. Any injury which may happen to the plate can be readily repaired.

COPYRIGHT IN BOOKS AND PICTURES.

A new Bill, based on the report of the Commission on Copyright, has been introduced by Lord John Manners:—

According to it the author of a book first published in Her Majesty's dominions will be entitled to the copyright throughout those dominions, whether he is a British subject or not, or whether he is domiciled or resident in those dominions or not. With regard to a book first published out of Her Majesty's dominions, the provision is that the author may acquire the copyright by republishing it in those dominions within three years from the first publication, if, at the time of the first publication, he is either a British subject or an alien domiciled in Her Majesty's dominions. In this case the copyright would date from their publication. The time for the duration of the copyright is thus regulated by the Bill:—If the book be published in the lifetime and under the true name of the author, the copyright would endure for the life of the author, and for thirty years after his death; but for thirty years only from the date of the first publication if the book be not published in the author's true name, or if it be published after his death. With regard to what would constitute an infringement of the copyright, not only would it be illegal to print a copy of the book without consent, but to print an abridgment or a translation of it, or to dramatize it by preparing or adapting it for representation on the stage as a dramatic piece, or to cause a dramatized version of it to be publicly performed. It is provided that no legal proceedings be taken or forfeiture in

curred in respect of any infringement of copyright until registration has been effected with the Stationers' Company. And to register, the proprietor must deliver to the Registrar a copy of the book, accompanied by a verified statement showing the name, address, and calling of the publisher and of the proprietor of the copyright, and the place and date of the first publication. If the author's true name is published, the statement must also include his name, address, and calling. The book thus delivered to the Registrar is directed to be sent on by him to the British Museum. Moreover, it is provided that the assignment of a copyright be invalid unless it be registered; and that every registered proprietor shall have absolute power of disposing of the copyright, with the exception that it is left open for rules to be made for caveats being entered against any such disposition. These and other rules for the regulation of registration are to be made by the Board of Trade, subject to the approval of Parliament. In the case of any work published in series, it is provided for the copyright of the whole to belong to the proprietor, as if he were the author of the whole, when the parts have been composed on the terms that the copyright in the composition shall belong to the proprietor. This rule is, however, subject to certain qualifications, among which is one which says that, except with regard to an encyclopædia, the proprietor of the copyright may not publish any of the compositions separately from the rest of the book without the consent of the author. And after three years from the first publication, the right of publishing the composition separately would vest exclusively in the author. The provisions of the Bill with respect to books published in series are made to apply to newspapers as regards original compositions of a literary character, but not as regards the portion containing news.

One of the provisions imposes no small burden on the British Museum in directing that the publisher of a newspaper must send a copy of every number to the Museum within a week of publication. With regard to lectures, it is provided that if they be other than those delivered in a university, public school, college, or public foundation, or by any person in virtue of or according to a charity, the author is to be entitled to copyright in them, just as if they were books. It will not, however, be necessary to register a lecture which is not published. As long as a lecture has not been printed and published by the author, a man will infringe the copyright if he delivers the lecture without the written consent of the proprietor. But a newspaper is not to be debarred from publishing a report of the lecture in the current edition, unless the author before or at the time of delivering the lecture gave notice of a prohibition. The copyright in dramatic pieces or musical compositions which are either printed and published or publicly performed, is subjected by the Bill to the following rules:—It is an infringement to perform one publicly, or any part of one, or any abridgment or adaptation, without the written consent of the proprietor. If a piece or composition is publicly performed, but not printed and published as a book, it may be registered without the delivery of a copy or a statement of the publisher's name. The first public performance or the first publication by printing and publishing as a book, whichever may be the earliest in date, is to be deemed the first "publication." When the first public performance takes place out of Her Majesty's dominions, copyright may be acquired either by a public performance or by publication as a book in those dominions within three years. Some annoyance would, no doubt, be saved by the provision that the purchaser of a printed copy of a musical composition is to have the right of publicly performing it, unless the copy contains on the title-page, or in some other conspicuous position, a statement that the purchaser will not have that right without consent, and also specifies the name and address of some person authorized to give the consent. And a purchaser who cannot with reasonable diligence find the person so specified, is authorized by the Bill to perform the piece without any consent. Moreover, where a musical composition is published with words, the proprietor of the copyright in the words is not authorized to prevent a person from using the words with the music at any public performance. Part 2 of the Bill relates to paintings, sculptures, engravings, and photographs; part 3 to colonial copyright; part 4 to foreign copyright; and part 5 contains some general provisions relating to legal proceedings and the like.

COPYRIGHT IN PHOTOGRAPHS.

The Bill enacts as regards photographs as follows:—

Painting.—1. The author of an original painting shall be entitled to copyright therein throughout Her Majesty's dominions, whether the painting is first published in or out of Her Majesty's

dominions, and whether the author is or is not a British subject, or domiciled or resident in Her Majesty's dominions, unless the painting is first published out of Her Majesty's dominions and the author thereof is not a British subject and not domiciled in Her Majesty's dominions at the time of the first publication.

2. Provided that there shall be no copyright in a painting unless the painting, and every copy thereof made with the author's consent before the painting is published, bears the author's name and the date of the execution of the painting.

Copyright in a painting published after the commencement of this Act shall endure for the following terms:—

(a.) If the painting is published in the lifetime of the author, for the life of the author and thirty years after his death.

(b.) If the painting is published after the death of the author, for thirty years from the date of publication.

Every person shall be deemed to infringe the copyright in a painting who, during the term of copyright, does, without the written consent of the proprietor of the copyright, any of the following things; namely—

(a.) Makes or causes to be made any copy of the painting; or (b.) imports or causes to be imported for sale or exhibition any copy of the painting made in any foreign country or made in infringement of copyright; or (c.) sells, publishes, exposes for sale, or exhibits, or causes to be sold, published, exposed for sale, or exhibited, or has in his possession for sale and exhibition, any copy of the painting made or imported in infringement of copyright.

Where a painting is sold or is executed on the order of any person for valuable consideration, the copyright therein shall vest in the purchaser or person on whose order it is executed, unless the author reserves it by written agreement.

Where the copyright in a painting is reserved by agreement—

1. The author shall not, without the consent of the owner for the time being of the painting, execute or authorize any person to execute any copy thereof; and the owner shall have the same right of preventing the execution of any such copy as if he were the proprietor of the copyright.

2. If the copyright is infringed the owner of the painting shall be entitled to take the same proceedings in respect of the infringement as if he were the proprietor of the copyright.

3. Provided that if the infringement is by any person other than the author, the owner, before he takes any legal proceedings in respect thereof, shall give to the proprietor of the copyright notice of the infringement, and of his intention to take proceedings in case the proprietor fails to do so, and shall give the proprietor an opportunity of taking proceedings to prevent the infringement.

4. The proprietor of the copyright shall, or if he fails after notice from the owner of the painting, then that owner may register the copyright in the painting by delivering to the registrar a statement, verified in the prescribed manner, showing the nature and subject of the painting, the name, address, and calling of the author, of the proprietor of the copyright, and of the owner of the painting, and the date of and parties to the agreement.

5. The statement may be in or to the effect of the form contained in the First Schedule to this Act, or in or to the effect of such other form as may for the time being be prescribed.

6. Until the copyright is registered, no legal proceedings shall be taken or forfeiture incurred in respect of any infringement of copyright in the painting.

7. Unless the copyright is registered within one month after the date of the agreement, no legal proceedings shall be taken or forfeiture incurred in respect of any copy made or imported before the date of registration, whether any such copy is sold or exhibited before or after that date.

Nothing in this Act shall prejudice the right of a person to copy or use any painting in which there is no copyright, or to represent any scene or object notwithstanding that there may be copyright in some representation of that scene or object.

Nothing in this Act shall prevent a person who has sold a painting from selling or using any models, casts, sketches, or studies made by him for the purpose of making the painting, so that he do not repeat or colourably imitate the design of the painting.

Sculptures.—1. The provisions of this Act with respect to paintings shall apply to sculptures as if they were herein enacted with the substitution of "sculpture" for "painting."

2. The author of a copy of a sculpture in which there is no

copyright, or which was copied with the consent in writing of the proprietor of the copyright, shall be entitled to the same copyright as if his copy were an original sculpture.

Engravings and Photographs.—1. The provisions of this Act with respect to paintings shall apply to engravings as if they were herein re-enacted with the substitution of "engraving" for "painting," subject as follows:—*a.* The provisions of this Act as to the name of the author and date of execution shall not apply, but there shall be no copyright in an engraving unless the name of the author is printed thereon. *b.* The copyright in an engraving shall belong to the proprietor of the plate, stone, or other instrument by means of which copies of the engraving are produced. *c.* Where the engraving is made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit, any copy of the engraving without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any copy of the engraving, and, if the copyright is infringed, of taking proceedings in respect of the infringement, as if he were the proprietor of the copyright.

The provisions of this Act with respect to paintings shall apply to photographs as if they were herein re-enacted with the substitution of "photograph" for "painting," subject as follows:—*a.* The provisions of this Act as to the name of the author and date of execution shall not apply:—*b.* The copyright in a photograph shall endure for thirty years from the date of publication of the photograph, and no longer:—*c.* The copyright in a photograph shall belong to the proprietor of the negative from which the photograph is printed:—*d.* Where the photograph has been made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit any copy of the photograph without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any copy of the photograph, and, if the copyright is infringed, of taking proceedings in respect of the infringement, as if he were the proprietor of the copyright.

The provisions of this Act with respect to the registration of the copyright in books shall apply to the copyright in engravings and photographs as if they were herein re-enacted with the substitution of "engraving" or "photograph," as the case requires, for "book;" except that where an engraving or photograph has not a distinctive title there shall be substituted for the title in the statement required on registration a short description of the nature and subject of the work.

General Provisions as to Works of Art.—Every person who commits any of the following offences; that is to say,—*a.* fraudulently signs or otherwise affixes, or causes to be signed or affixed, on or to any painting, sculpture, engraving, photograph, or negative of a photograph, any name, initials, or monogram; or,—*b.* fraudulently sells, publishes, exhibits, offers for sale, or exposes for sale or exhibition, any painting, sculpture, engraving, photograph, or negative of a photograph, having thereon the name, initials, or monogram of a person who did not make the painting, sculpture, engraving, photograph, or negative; or,—*c.* fraudulently sells, publishes, exhibits, offers for sale, or exposes for sale or exhibition, any painting, sculpture, engraving, photograph, or negative of a photograph, as having been made by the author of the original work of which it is a copy or imitation; or,—*d.* Where a painting, sculpture, engraving, photograph, or negative of a photograph has been sold, and subsequently altered during the life of the author and without his consent, knowingly sells, publishes, or offers for sale, the work so altered, or any copy thereof, as, or as a copy of, the unaltered work of the author, shall be liable to a fine not exceeding *ten pounds* and double the full price, if any, at which any such paintings, sculptures, engravings, photographs, or negatives have been sold or offered for sale, and this fine shall be paid to the person aggrieved.

2. Every work which has the name, initials, or monogram of any person so fraudulently signed thereon or affixed thereto, or which, being spurious or altered, is so fraudulently or falsely ascribed to any person, shall be forfeited to that person, or his assigns, or legal personal representatives.

3. Provided that no penalty shall be incurred under this section unless the person whose name, initials, or monogram is or are used, or to whom a spurious or altered work is ascribed, is alive at the time when the offence was committed, or was alive within twenty years before that time.

Where an engraving or photograph is published as part of a

book containing letterpress, it shall, for the purposes of this Act, be deemed part of the book, and not an engraving or photograph; and the copyright in the engraving or photograph shall belong to the proprietor of the copyright in the book.

Correspondence.

THE PHOTOGRAPHIC ARTISTS' CO-OPERATIVE SUPPLY ASSOCIATION.

SIR,—If "Kaleidoscope" means to insinuate that the P. A. C. S. A. "entice shareholders by a fictitious business," or conduct business upon any but strictly honourable principles, I beg to give him the most unqualified denial.

The Association has been well received by photographers and manufacturers; the dealers or middle-men alone object to it.

The object of "Kaleidoscope's" anonymous and unjustifiable attack sufficiently appears by the tone of his communications.

The benefit already conferred upon photographers by the Association is shown by the reduction in prices which many dealers have offered—for cash—since the Association commenced business.—I am, sir, yours obediently,

H. KERR,

Managing Director P. A. C. S. A., Ltd.

43, Charterhouse Square, E.C., Aug. 18.

[We regret exceedingly that Captain Kerr or the P. A. C. S. A. should find in the "Gup" of *Kaleidoscope* any insinuation as to their mode of conducting business. We can, and we willingly do, give them the fullest assurance that no motive could exist to induce our contributor to indulge in any such insinuation. On our own part, if we had seen the slightest doubt implied as to the strict honour of the Association and its management, we certainly should not have permitted it to appear, and we regret that the possible construction of the paragraph should have caused them annoyance. As regards the principles of co-operation, this is not the place to discuss them. No one can for a moment be weak enough to imagine that co-operation, as a system, involves anything censurable or unworthy, or that its application to photography can be more objectionable than it is to the distribution of sugar, cheese, and bacon, in relation to which form of co-operation the public seem to be very well satisfied.—ED.]

SIR,—I do think your "Gup" writer is not warranted in speaking of the P. A. C. S. A. in the way he has done. Let me tell him that my first little order for about £3 saved me 14s., and I can tell him of a dozen photographers who can give him the same experience.

I suppose my account with the Stores will amount to between £500 and £600 per year.—I am, dear sir, yours,
A PHOTOGRAPHER.

[Our correspondent should have remembered that to give weight to his letter he should have signed his name, as the mere signature "A Photographer" possesses no authority. In order that his testimony may duly represent the value it really possesses, we may add that he is one of the most skilful and successful of metropolitan portraitists.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF IRELAND.

A MEETING was held at the Queen's Institute, Molesworth Street, Dublin, Wednesday, the 13th of August, 8 at p.m., the vice-president, Mr. HOWARD GRUBB, F.R.A.S., in the chair.

The minutes of the preceding meeting having been read and confirmed, five new members were proposed for election at next meeting.

Mr. GEORGE MANSFIELD detailed his method of preparation

of gelatino-bromide plates, and drew attention to the fact that the long and troublesome process of digestion might be obviated by forming the bromide of silver in a very weak solution of the gelatine, which was then boiled for about ten minutes, the remainder of the complement of gelatine in the formula being added when the first solution had cooled down to about 100° Fah. The formula used was a slight modification of Mr. Bennett's with Nelson's No. 1 gelatine. The emulsion thus produced be found sufficiently rapid for the ordinary landscape work of most amateur photographers, and fully capable of rendering good negatives. He found that the addition of one ounce of strong methylated alcohol to every ten ounces of emulsion ensured its keeping good for at least many months. He also advocated the omission from the developer of the bromide generally used; and certainly the large negative shown left nothing to be desired on the score of cleanness. The development took place as quickly as with a wet plate. The discussion which followed us to the desirability of extreme rapidity for landscape work, and as to the capability of the gelatine process of rendering the detail in shadows, clearly showed the wide divergence of opinion on the subject.

Mr. ALEXANDER CONAN described the preparation of plates, using, instead of Nelson's No. 1 gelatine, Swinbourne's isinglass, which he found had very many advantages over the former, being more easily worked in warm weather, and not so liable to frill or blister. The plates, as shown, were very free from all blurring, remarkably clear in the shadows, and of a good printing density and colour. They were not, however, as rapid as Swan's plates, and he found, when endeavouring to increase the rapidity, that the difficulty of avoiding fog was considerable. One of Rouch's new patent cameras for 12 by 12 plates was exhibited, and was almost unanimously approved of for its extreme lightness and portability. The replies to the interrogations in the question-box having been disposed of, the meeting adjourned until Wednesday, the 10th September.

Talk in the Studio.

PERSIAN AND ENGLISH ART.—Those of our readers interested in perfect design in art-industries should call at the show-rooms of Messrs. Hukin and Heath, 19, Charterhouse Street, Holborn Circus, where they have now on view some very charming examples of Persian art in gold and silver. Some examples of design by Dr. Christopher Dresser in electro-plate are singularly fine, and worth examination. Simplicity, severity, and perfect function, characterize every piece. The whole display will well repay a visit.

THE WEATHER.—Mr. James Glaisher has supplied to the Registrar-General a short history of the bad weather which set in on the 17th of October, 1878. He has to state that the mean temperature of the eight months ending June, 1879—namely, 41°·65deg.—is the lowest since the celebrated year of great frost, 1814, when it was as low as 40°·4deg. The instances of such low temperature in the last 100 years are those:—In 1783-84 the mean temperature of the eight months ending June was 41°·3deg.; in 1784-85 it was also 41°·3deg.; in 1788-89 it was 41°·2deg.; in 1794-95 it was 40°·9deg.; in 1796-97 it was 41°·3deg.; in 1813-14 it was 40°·4deg.; in 1815-16 it was 41°·7deg.; in 1854-55 it was 41°·9deg.; in 1878-79, 41°·65deg. The weather following June in the years 1784 and 1785 was cold; in the year 1789 it was cold, excepting in December; in 1795 it was cold in July and November; in 1797 it was cold, excepting in July and December; in 1815 it was cold, excepting for a very warm September; in 1855 it was moderately warm to October and cold in November and December. Therefore, as a rule, the same cold weather has continued throughout the year. This is all the comfort Mr. Glaisher has to offer.—*Times*.

To Correspondents.

R. L.—We regret that the article on the dark room must be delayed for a week or two. We will give attention to the point you mention in it.

J. S.—Your rectilinear lens is most suited for architectural and general work.

BROMIDE.—You will find it wise, in commencing the use of gelatine plates, to read up what has been written on the subject in the present and last volume of the NEWS, and in the last YEAR-BOOK. Very much attention has been given to the subject of frilling and the remedies for it, such as alum, methylated spirit, &c. In Mr. Jarman's useful practical articles (see NEWS, July 11th and following number), you will find that in his experience the use of methylated spirit in the developing, fixing, and washing solutions proves a perfect cure.

PRINTER.—Some of the stains are clearly due to hypo, and have been caused by contact with other prints containing hypo. That of *Lodore* is clearly an example of such a case, as the impress of another print with its corner turned up is clearly there on the back of that sent to us; and the markings are due to contact between hypo and silver. The other large print bears a somewhat similar mark, and the stain is from the same cause. The other stains are probably due to a similar cause in a much slighter degree; some are scarcely marked at all. The photographs are good, and well printed. Do not pack quite so firmly in futuro. We could scarcely get the parcel undone without tearing up photographs and the letter in which they were wrapped.

CURATOR.—The black and white of which you speak may be obtained with almost any toning bath. It depends chiefly on the negative. With a good intense negative which permits deep printing you can get any tone. The lime bath is, however, generally most conducive to black tones. Take 2 grains of chloride of gold, and 3 grains of chloride of lime, and dissolve in 16 ounces of water. Allow it to stand twenty-four hours, then use. Remember deep printing is imperative, and little or no washing before toning.

W. W.—The defect in the print you enclose is due, most probably, to imperfect fixation. The hypo solution may have been weak, or partly exhausted, or the temperature of the solution may have been very low, and its solvent powers very slight. In any of which cases a portion of insoluble hyposulphite of silver being left in the print produces, when it becomes decomposed, the dirty mottling seen in the prints. It might possibly arise from the presence of hypo in the mounting cards, which would produce a similar result; but we do not think it likely to be the cause here. 2. We never used a substratum of albumen for opal collodio-chloride pictures, because we believe that albumen conduces to fading, either on paper or glass. Many writers on the subject strongly recommend the preliminary coating of albumen as aiding in securing perfect adhesion of the film, and also in securing a richer and more vigorous image. We, you will find, have never recommended such a substratum, but merely an edging of it to secure adhesion when a tough collodion is used. 3. You will find a letter this week.

A. C. B.—There is no preparation which applied to prints before rolling will give them a surface like enamelling. We know of nothing but enamelling which gives a similar surface. Burnishing, after using a solution of Castile soap in alcohol, gives a very high surface, but not equal to enamelling. Encustic paste improves the print, but does not give a surface like enamelling. Thanks for hint. This answer has been delayed.

SEARCHED IN VAIN.—We do not know the name of the maker of Field's Patent Tent. Possibly some of our readers can inform us and our correspondent.

B. L. M.—The gelatine emulsion processes generally are quite open to the use of everybody, and free from what you term patent trammels. Mr. Kennett holds a patent for a special mode of preparing his pellicle, but you may make and use gelatine emulsion without trenching upon the rights or claims of anyone. Some of the commercial methods are secret; but there are plenty of excellent methods published fully. 2. We cannot very well advise you whether to make your own emulsion, or to purchase plates or materials. Perhaps, at least for a beginning, it would be wise to purchase ready prepared plates; then if you succeed, and like the results, you may try your hand at preparation of your own plates.

R. GOODEN writes to say that a photograph, registered by Mr. Poole, of the Prince of Wales laying the foundation stone of the Royal Hospital for Incurables, is not the copyright of Mr. Poole, who only acted as assistant to Mr. Gooden, who was really commissioned to do the work. Our correspondent will have a definite remedy under the Copyright Act if he can substantiate this statement in a court of law.

J. G.—We do not know any house which makes metal window frames suitable for skylight. Perhaps some of our readers can give information.

B. B., J. C. BURROW, ERNEST KAVANAGH, and other correspondents, in our next.

Several correspondents in our next.

The Photographic News, August 29, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.
ADVERTISING BEAUTIES—WHAT LEAVES TO TAKE, AND
WHAT TO LEAVE ALONE.

Advertising Beauties.—We are afraid photographers are responsible for a good many of the vanities of the day. We are not going to charge them with anything so had as the introduction of crutch and toothpick, nor, indeed, to pandering to that particular vanity, for although, as a popular song has it,—

"I've been photographed like this,
I've been photographed like that,"

we cannot call to mind having seen a picture of a soi-disant swell with these implements in hand. The originators of the silly custom were probably the gents who are so used to having yard-measure and scissors in hand by day, that they must perforce have something to replace such things by night. But the photographer has his sins, nevertheless, for he is responsible, in a great measure, for that objectionable person—the professional beauty. A lady whose profession it is to be a beauty, and to appear in that character at fancy fairs, would scarcely, one would think, hold a very exalted position; but, thanks to photographers, she has become a very grand personage indeed. She at once takes rank with other notables, with royalty, science, and distinguished murderers. Love levels all; but photography, according to a modern author, is quite as powerful a leveller; you are all put in the same row in the shop windows. They are all stars that are seen there, and, as happens in the firmament, the falling stars show more brilliantly than the rest; they are the most attractive, and hence they are placed "twixt a bishop and a queen." The professional beauty dazzles nearly as much as a falling star, and as she has any number of bewitching dresses at her command, it is only to be expected that, once she has chosen her calling, she should have followed it up and be photographed like this and photographed like that. Actors and actresses doubtless indulge in the same weakness, but in their case there is, at any rate, some excuse. With them, to be portrayed is another mode of advertising, quite as legitimate as the puff paragraphs that appear in the papers, while to be photographed like this and photographed like that is with them simply a representation of various characters. We do not, moreover, look upon their pictures simply because they happen to be well-looking, but because the portraits remind us that the originals have more or less brains. But with the professional beauty, the matter of brains does not come under discussion at all; the case is just the reverse of the spry young *Americaine*, whose speech was, "I mayn't be pretty, but mother says I've got the intellects in me." Now the professional beauty's own duties are to attend fancy fairs and be photographed. They are probably as harmless occupations as can well be conceived, and seeing that the photographer must benefit a good deal by them, it is not likely he will think very harshly of the lovely creatures with whom he has to do. But, nevertheless, he is responsible in a great measure, at any rate to society, if he is not the *raison d'être* of the professional beauty. In the fashionable annuals of forty and fifty years ago there were representations of the belles of society now and then, no doubt, but these florid works had but a limited circulation, which was practically confined to the upper ten. But nowadays, the supply of these portraits is to the public generally, and you may purchase the charming Mrs. A. or Lady B. for sixpence, a shilling, or may be a florin, according as she is photographed like this, or photographed like that. We don't know what Mr. A. or Lord B. thinks about it, but to our mind the least happy application of photography is certainly to devote it to the depiction of women whose sole object in life is to present themselves to the public as much as possible so as to establish a repu-

tation in society like that enjoyed by Moses and Son among tailors, and Harper Twelvetees among the manufacturers of subtle compounds for the destruction of domestic insects. Photographers and Society journals must share between them the onus of having invented such a purposeless creature as the professional beauty.

What Leaves to take, and what to leave alone.—We have a suggestion for one of our clever landscape photographers. It is that they should write us a paper on the photographing of foliage, telling us the kind of trees that are the more easy to depict, for foregrounds especially. It is not unfrequently the case that in selecting a foreground for a landscape you have choice of several kinds of foliage, and the difference between a practised hand and a novice is, that the former chooses leaves that he knows to be steady, while the latter hardly gives the subject a second thought. Even if they are in a sheltered position, the leaves of a Lombard poplar are never still; they are balanced upon a slender stalk which does not remain steady for an instant. "Come when the aspens quiver," is scarcely good advice to an outdoor photographer, and yet one sees the depiction of such foliage attempted over and over again. An old hand, however, never does anything of the sort. He chooses a good stout leaf that it takes half a gale to stir. The vine leaf furnishes a capital foreground, and the photographer in South Germany, in Italy, and in the Tyrol can usually secure it in his pictures. We have in our mind's eye at this moment a charming view of Mr. Woodbury's, taken near Menaggio. We look over the placid waters of Como to the soft promontory of Bellagio, and can see the Lake of Lecco beyond as bright and still as a mirror. In the foreground of this composition is a trellised vine, the leaves as sharply depicted as if they were silhouettes cut out in paper. Mr. H. P. Robinson, the other day, told us that the horse-chestnut was one of his favourite models, and those who have studied that accomplished photographer's work will remember that he has frequently limned the chestnut in his pictures. In some of his pictures Mr. Robinson has been able, indeed, to secure a photograph of the under-side of the leaves of his favorite tree, a *tour de force* which is not easily accomplished. The fig tree is another good friend of the photographer, and some of the ivies too; not all, however, for the ivy leaf has frequently a long stalk, and then trembles with the best of them. But a vine of ivy twisted round a bare fence or gate will frequently make all the difference in a picture in which fence and gate are prominent objects. We need not, indeed, dwell upon the charm which foliage imparts to the foreground of a landscape, but the foliage must be well rendered if it is to occupy a prominent place. Steady leaves and spots well sheltered from the wind are essential, while we may also remark that if the photographer pursues his out-door work in early summer, when the leaves are not fully out and firmer on the stem, he will have an easier task. But here we must leave the subject, hoping that a Bedford or England or Manners Gordon will, at some future time, give us a practical paper on foliage that is easy to photograph

FRENCH CORRESPONDENCE.

PHOTOGRAPHIC LITERATURE—REMONSTRANCE OF M. DUCOS DU HAURON—TRIAL OF A PHOTO-ENGRAVING PROCESS IN M. DIDOT'S WORKSHOPS—DEVELOPING SOLUTION FOR AN INSTANTANEOUS PROCESS BY M. DARRICAU—THE FRENCH PRESIDENT AT THE EXHIBITION OF SCIENTIFIC WORKS APPLIED TO MANUFACTURES.

Photographic Literature.—The lecture delivered at the Sorbonne in March last by M. Davanne, on "Photography, its invention and applications," has just been published by the house of Gauthier-Villars. It will be recollected by your readers that I gave an account of this lecture at the time (see PHOTOGRAPHIC NEWS for 10th of April, page 175), and spoke in very high terms both of

the ability of the lecturer and of the manner in which he was received by his audience. I also expressed my vivid satisfaction at seeing the doors of that strictly scientific institution, the Sorbonne, opened to admit a discussion on photography. I recur to the subject on the present occasion for the purpose merely of bringing the publication of the lecture to the notice of readers of photographic literature. Works on photography keep growing in number and importance, though even now a photographic library could be collected of great value and interest. M. Gauthier-Villars has determined to offer every facility for publishing in France all the treatises and books bearing on photography, and thanks, to him, the number of such works is rapidly increasing.

Remonstrance by M. Ducos du Hauron.—I have recently received from M. Ducos du Hauron a letter of which I give the following extract, in order to show the spirit in which he meets my criticisms on his process of heliography in natural colours:—"It is quite certain," he says, "that the three colours, or pigments, whose exact or (what amounts to the same thing in practice) approximate tonality several years of close study and experiment have enabled me to determine, are able actually to represent, by means of their optical superposition, all the hues of nature, infinite though they are supposed to be. Copying the most complicated colouring, or the most gradual and delicate change of tint, costs by my method no more trouble than copying a rough illumination of Epinal. Always three negative plates—not one more nor one less—three negatives taken through three coloured media, invariably the same; afterwards a threefold printing. Such is my method—my immutable method—which can be worked by any of the processes: the gelatine process, that with engraved plates, that with fatty inks, &c. Now is this method not much superior, and has it not a more promising future, both artistic and industrial, than that which, to produce a richly-coloured chromo-lithograph, requires twenty and odd different printings? Can a work of excision and adjustment by bits and pieces, like the fitting together of a mosaic, ever be as valuable as this threefold distribution, and this re-constitution of the constituent elements of colour by the sun itself?" Now all this is said, and very well said, with a conviction which certainly commands respect. I have already shown too much scepticism as to the possibility of practically and artistically obtaining with three colours all the natural shades and tints, to discuss the question again; I propose to abstain from expressing any further doubts on the subject until there are brought forward the convincing proofs which this investigator, as opinionated as he is indefatigable, has promised us. At the meeting of the Photographic Society of France, which takes place on the 9th of next month, M. Ducos du Hauron proposes, as he informs me, to exhibit some new prints taken by his method of *heliographie*, measuring 21 by 27 centim., a much larger size than any that he has previously produced. Their author appears to be quite satisfied with them, but until I have seen them I shall reserve my opinion—an opinion which I shall form without reference to my former criticisms. As far as this method of M. Ducos du Hauron is concerned, just as much as regards any other system or process, I wish it to be known that I always speak quite as I feel, and never under the influence of personal interest. I have only one interest, and that is (no one will censure me for avowing it) the interest of the progress and success of the art of photography in all its forms and all its applications. If I have been led oftener than I could have wished to express doubts as to the value of the process of M. Ducos du Hauron, it is entirely owing to the fact that this process is designated by a title which can scarcely be justified. The name of *Heliographie Naturelle* can only mislead if it be applied to a process which is far from realising the conditions which such a term implies. The correct title for this process would be *Polychromie Photographique*. Let the qualification *Naturelle* be sup-

pressed, and I shall be in a position to follow with interest and sympathy the experiments and work of the inventor of the process, without being compelled to protest, so continually as I have been (in the name of liberty of judgment and by right of my sincere conviction) obliged to do, against what, in my opinion, is the impossibility by this method of reproducing the effects of nature in its most delicate tints, however infinite may be their number. I must entirely disclaim the imputation of having acted as I have done merely in order to offend a respected colleague; on the contrary, I entertain too high an esteem for him to do anything else but manifest the courage of my own opinion. But I promise him to retract anything I may have said, and to confess myself in the wrong, directly that, in spite of my present attitude of scepticism, indisputable proof is given of the truth of the evidence which is claimed as favouring the process, but of which I have hitherto always had grave doubts. I shall then not hesitate a moment in tendering him my sincere apologies, and the praise which, in that case, I shall not be slow in bestowing, will have all the more value from the fact of its having been preceded by strictures frankly expressed, and by criticism the result of conviction. The rôle of a chronicler of events in the photographic world is not the most agreeable to play; if he praises anything, he is accused of advertising the processes or the inventions of A or of B; if he finds fault, then it is said that he is actuated by malice, that he bears an ill-will against C, and is trying to spoil his business and to ruin his prospects. Evidently the best way would be to *say nothing*, while to *do nothing* would be the acme of perfection. Now I am well aware of this, and sometimes I am inclined to envy the comfort enjoyed by the man who says and does nothing; but with me, to whom activity is a necessary of life, this feeling of envy does not last long; I get to work again, and console myself with the adage—one which has always inspired my rule of conduct—"Faire bien, et laisser dire."

Photo-engraving Process as used in the Printing Office of M. Didot.—Some time ago I had occasion to mention in the PHOTOGRAPHIC NEWS (see No. 1087, 4th July, page 320) a method devised by M. Petit for producing photo-typographic plates, which has been tried in the workshops of the house of Firmin-Didot. I have just heard that in consequence of the success of the first trials, special machinery has been put up in these shops for working plates of the size 30 by 40 centim. As far as I have been able to learn, this process, whose value can only be proved by time, consists in the production of prints striated in different directions, so as to form hatchings, which can then be transferred to zinc, either for working with fatty ink, or by means of bitumen, when the lines are etched in by the ordinary method. M. Petit proceeds in the following manner:—A gelatine plate, similar to one which is taken by the Woodburytype process, is first obtained from the negative of the object to be copied on the printing block. By means of strong pressure an impression is then taken warm from this gelatine plate in some white plastic material which is capable of hardening as it cools. We have thus a number of depressions in the white material corresponding to the reliefs, more or less pronounced, in the gelatine; we have, in fact, an impression similar to that taken on the leaden plate in the Woodburytype process, but it is in a material of a white colour analogous to a plaster casting, and this, as will be seen, is a most important point in this process. All the surface of the impression is then blackened with graphite, and over it is made to pass the point of a hatching machine, this point being so arranged that when it rises it gives a broader line, and the depth of the cut being limited by the greatest depth of the depression. Now the impression being, as a matter of course, placed in a perfectly horizontal position, it follows that the cuts or hatched lines are more or less wide according as the depressions over which they pass are more or less deep. To the most prominent relief—or, better, to the least marked depressions—

will correspond the most coarse-grained hatchings, and the latter will become finer according as the indentations are deeper. The cuts are all white, and finally we have a drawing of which the shading is formed of white hatchings on a black ground, for all the parts previously coated with plumbago, and not touched by the point, remain black. It will readily be understood that from a drawing of this kind a negative can easily be reproduced in the camera, from which positive prints can then be taken on zinc plates. There can scarcely be a more favourable augury for the future of the applications of photography than to see them promoted in this way by a house so important as that of Firmin Didot. Although I have seen an engraving executed by this process of M. Petit, I can scarcely venture to pronounce an opinion on the probability of its success while the process itself is still in the stage of infancy; when, after being worked on a large scale, its results are before the public, I shall be better able to do so. The idea of these hatched lines is certainly not a new one, but that fact is of no importance provided that the process succeeds in realizing an industrial progress. When the application of a discovery is under consideration, whether the idea which lies at the root of it is new or not is a matter of no moment; what we want to know is, whether it can be successful in practice; the question of priority is rather one of moral and historical interest.

M. Darricau's Formula for an Instantaneous Process.—One of my esteemed correspondents at Marseilles has sent me—*apropos* of the process of M. Boissonas, as published in the PHOTOGRAPHIC NEWS—the formula for a developing solution by means of which, in his opinion, a picture may be taken with a good light by merely opening and closing the flap of the objective—that is to say, in less than a second.

Distilled water	100	grammes
Saccharo-sulphate of iron...	12½	"
Glacial acetic acid...	50	drops

The tone of the negative he describes as being very rich, and similar to that obtained with pyrogallic acid. To this formula M. Darricau appends one for the preparation of saccharo-sulphate of iron, which is not found in the market:—Dissolve (1) 100 grammes of ferrous sulphate in 100 grammes of boiling distilled water; and (2) 50 grammes of sugar-candy in 30 grammes of boiling distilled water; then mix the two solutions, and in a short time crystals will be deposited. Collect these crystals and put them to dry on a sheet of white blotting-paper, but carefully avoid using the rose or buff-coloured paper; this precaution is essential.

Visit of the President of the French Republic to the Exhibition of Scientific Works applied to Industry.—I should not have referred to this event except to take advantage of it for the purpose of explaining the position which photography occupies at the Exhibition. In my quality of joint commissioner with M. Davanne, I was in attendance on the President of the Republic during his peregrination of all the sections of the Exhibition (which, notwithstanding its name, is rather industrial than scientific in character) on the occasion of his official visit to it on the 22nd August last. The most noticeable circumstance of this ceremony, so far as we were concerned, was that M. Grévy was not conducted to the gallery where the photographs are exhibited, and the reason for this omission is not far to seek. The gallery in question is half empty, and to prevent attention from being drawn to the nakedness of the walls, the Director of the Exhibition avoided bringing his distinguished visitor to see them. For this unfortunate state of things neither the exhibiting photographers, nor the commissioners charged with the organization and arrangement of the photographic section—that is to say, M. Davanne and myself—are responsible. We were allotted only the half of one gallery, and were told that the other half had

been set apart for elementary education. Unfortunately, we soon found that this space, which could not be given up to us, was not likely to be occupied by any one else, and, in fact, it has remained empty up to the present day. The result is most deplorable, and even detrimental to the interests of the Exhibition in the photographic section, for the public, disgusted at the bare condition of the gallery, has no inclination to spend any time in it. Under such circumstances, is it just to upbraid the photographers of France for refusing to exhibit, or to lay blame on those who do exhibit for being so few in number? I cannot admit the justice of such a complaint. We have only just done with the International Exhibition of 1878, and we ought really not to require exhibitors to be so soon ready for another. French photographers responded with remarkable unanimity to the appeal that was addressed to them to exhibit in the building in the Champ de Mars, and scarcely have they left it, scarcely have they removed the dust from their frames and their scutcheons, than they are asked to bring them forth again for a fresh field of competition. Now this is too much to demand of them; they had much better employ their time in improving themselves, in producing new work, in applying new processes, and then, when they do again come forward, they will rest their claim for a higher award on the progress they have made, not on the works which have already been submitted to the judges. What astonishes me—and I do not hesitate to say so—is that so many as thirty or thirty-five exhibitors in the photographic section have been found to respond to the appeal addressed to them by M. Nicole, the able Director of this Exhibition. To the individual labour, one may almost say to the personal initiative, of M. Nicole this very interesting exhibition is due; it is, in fact, for him an industrial enterprise; but this does not in any way detract from the merit of its promoter, nor does it lessen the value of the services which an undertaking of this kind is able to render. LEON VIDAL.

AUTOTYPE.

A RECENT notice in the *Art Journal* of carbon printing contains some interesting remarks. It says:—

“For about ten years, a process of photographic printing yclept ‘autotype’ has been growing into notice, and asserting its right to occupy the field of art photography. It not only claims to have solved the problem of rendering the photographic image inalterable, but, by the command of a wide range of monochromic effect, and of different surfaces for the reception of the picture, to have rendered practicable the reproduction of an artist's work in fac-simile. For example, an artist expresses his ideas in charcoal, in crayon, in sepia, or red chalk; the process is able to replicate his work, the same size, or larger, or smaller, employing the pigment of the original and the same kind of paper or foundation. The copy in such case may reasonably be believed to be as permanent as the original. A drawing or other artistic work reproduced by ordinary photographic means is palpably but a photograph; printed in autotype it will be so close a fac-simile of the original as not easily to be distinguished from it.

“The autotype thus claims, under favorable circumstances, to reproduce the very body and soul of an artist's work—his touch and sentiment, with the actual pigment of his palette and the material he works upon. Effecting this by chemical means without the intervention of another hand, the process found a sponsor to name it autotype.

“The starting point of all photographic pictures is the production of a negative in the camera. The negative becomes a matrix of endless prints. Most of our readers are familiar with a negative, and have noticed how the lights and shadows of the image on the glass are reversed; the

high lights of the subject being represented by a dense deposit, while its shadows approach the condition of clear glass. It follows that light will be retarded in its passage through a negative exactly in proportion to the varying density of the image on its surface, and the art of photographic printing consists in providing that the transmitted light shall impinge on a surface sensitive to its impression. This has hitherto been effected by the use of a paper coated with a thin substratum of albumen and rendered sensitive to light by a salt of silver. Photographs so produced are liable to gradual spontaneous decay, and fade away to the pale ghosts of their former selves, and ultimately disappear.

"Autotype claims permanency for its *raison d'être*. The difference it imparts into photographic printing consists principally in substituting for the fickle salts of silver some permanent pigment as the physical basis of the picture. This substitution not only supplants the evanescent by what is practically inalterable, but endows photographic art with the wide range of monochromic effect. Photography in natural colours is still a dream, but autotype is able to make some slight advance towards art in this direction. The process is founded on the property of gelatine when combined with a bichromate salt to become insoluble in water, after having been exposed to light. Paper is coated with a film of liquid gelatine containing finely ground colour and sufficient of the bichromate salt to insure chemical action. This sensitive tissue, kept from the light, is perfectly soluble in water; but if light acts upon it, the whole condition is altered: the gelatine becomes insoluble, and firmly imprisons every particle of the colouring matter. It will now be understood that if this sensitive tissue be placed under a negative, and exposed to light, the chemical action exerted upon it will be in proportion to the density of the negative; where much light passes, the tissues will be deeply penetrated, and much colour imprisoned; where the light is partially intercepted less colour will be fixed, and a latent picture will be formed in the tissue in exact gradation, and with the lights and shadows as in nature.

"To make this latent picture visible, it is, in technical language, developed by the action of warm water, washing away such portions of the coloured gelatine film as have not been influenced by light. But effective development is only possible by an ingenious operation known as transfer. The impact of light through the negative on the surface of the tissue has rendered that surface insoluble, and to achieve success, the pictorial film must be attacked at the back, that is, at the surface resting on its paper support. The various methods of effecting this constitute an important part of the autotype patents.

"The sensitive tissue which under the negative becomes fecundated by light is called the 'temporary support,' and the surface of this is made to adhere by pressure to the material on which the picture shall finally remain. This 'permanent support' may be drawing-paper, canvas, panel, ivory, or, in fact, almost any material used by artists. The two adhering supports are immersed in warm water, which softens the gelatine and allows the original paper or temporary support to be peeled off, and thus lays bare to the action of the water all the pigmented gelatine unaffected by the light. Under the solvent action of water, the picture gradually appears, and remains firmly adherent to its support. The lights and shades of this picture are built up by various degrees of thickness in the gelatine and pigment, representing exactly the gradations of density of the original negative, and the consequent modifications of the action of light. The developed pictures, after being immersed in a solution of alum, washed in pure water, and hung up to dry, are trimmed and mounted in the usual way. Such photographic pictures consist of particles of pigment held together by an incredibly thin film of gelatine rendered insoluble by chemical agency."

TRANSFERRING PHOTOGRAPHIC IMAGES.

A CORRESPONDENT of the *English Mechanic* gives the following details of a method of transferring photographs to wood or any other suitable substance.

It is the invention of Herr T. Pixis, of Munich, and has been patented. A phototype plate, representing the picture that is to be transferred, or its negative, is produced: it must be of the same size as the copy is to appear. The printing-ink used in the phototype process, to which any tone of colour may be given, is carefully mixed with a siccatif, Japanese gold size being preferred. The quantity to be taken of this liquid depends on the question whether the picture is to dry rapidly or slowly. As a rule, fifteen to eighteen drops of Japanese gold size to each half cubic inch of printing-ink may be considered adequate for producing that indelibility which must be attained in most cases. The photographic picture, after having been rolled over with this preparation, is transferred upon the material either directly or by means of transfer paper. The transfer upon ebony or upon any other dark material takes place by means of a white colour prepared in the above manner, or of any desired light colour. But the negative required for producing the phototype plate must in this case be converted into a positive, which may be done by the gelatine process. A thin white paper, one side of which has been prepared with an entirely smooth layer of paste and well pulverised chalk, or in some instances only with a thin layer of paste, must, in dry condition, be so placed upon the phototype plate, carefully impregnated with the above ink composition, that its prepared pasted side lies underneath; the paper is then softly pressed with a damp sponge, whereupon the whole is drawn through a press, if possible but a single time. The paper to which the picture has thus completely been transferred is then carefully taken off the plate, and can be immediately transferred on other materials, or it may be kept for the purpose of being transferred at a future time. In order to keep it damp for the latter purpose, it must be placed between damp blotting-paper and hermetically packed up. The object to be printed must be fastened in the press, and the transfer paper, after having been moistened from the reverse, is laid on that part on which the picture is to appear. Some sheets of damp blotting-paper are then placed upon the transfer paper, and the whole, together with the usual cover, is drawn through the press once or several times, according to the object upon which the transfer is being made; this done, the transfer paper is moistened with a sponge dipped in cold water until it can easily be detached from the transferred picture without leaving on it any traces of the printing-ink. In order to render the picture completely clear, the layer of chalk attaching to it directly after the act of printing must be removed by means of a soft sponge which has been wetted in cold water. Boxwood blocks are prepared for the process in the following manner:—A quantity of flake white ground in oil, such as is used by painters, must be mixed with a few drops of Japanese gold size, and as much benzine added as will make it possible to work the whole in the thinnest quantity attainable, and very swiftly, by using a broad brush. When the wood-engraver has finished his task he removes the white with turpentine or spirit. Upon smaller objects, such as medallions in ivory, metal, wood, &c., the transfer, if executed without delay, can be performed directly from the paper by using a smoothing-bone; this fact is important with regard to all such objects as are not quite flat, but somewhat vaulted.

In order to transfer a picture on porcelain, clay, or glass, Herr Pixis takes exclusively enamel colours, and gets them upon the phototype plate by rolling. If the tone of the picture is to be lowered or strengthened, or if a variety in colouring is desired, either the phototype plate, the transfer, or the material, is powdered over with dry colours of the required tint before the enamelling takes place, and while the pictures are still damp. This powdering with dry colours may also be applied to pictures which are to be transferred

to leather, textile fabrics, metals, wood, minerals, &c. The above-named materials, as likewise painted canvas, wood, metal, &c, may also, after the picture has been passed over, and before the transfer takes place, be prepared in the desired colour by means of oil, distemper, wax, porcelain, and water colours. Every picture, if transferred in the described manner upon wood in several colours or one colour, may, when sufficiently dried, be polished, oiled, and otherwise treated without becoming damaged. Pictures transferred on textile fabrics can be made to stand washing by drawing them, when dry, through a solution of glaire, squeezing and heating them to a temperature of 110-120° C. (230-270° Fahr.)

CONTROLLING LIGHT BY SCREENS.

VARIOUS forms of screens and reflectors have been devised for controlling light. Mr. G. W. Coddington, in our Philadelphia contemporary, gives details of a somewhat elaborate contrivance. He says:—

It is only intended for busts and the general figure, although children can easily be taken full-length. Neither is it intended for a small operating-room, for it would only be in the way, and the light in such small rooms can be easily regulated by top and side-screens and blinds. In using the platform I generally let in all the light I can get from the sky and sidelight (but not sunlight), and then regulate the screens, blinds, and reflectors attached to the uprights on the platform, and by moving it to different positions under the skylight, in conjunction with screens, &c., I can get any light I want with very little trouble. Everything is almost under your thumb, and you can keep your eye on your subject all the time while making any necessary changes, and do not have to run all over the room to pull this string or that blind, and by the time you have got back forget or cannot see any change in the effect, without it is outrageous, and very likely just what you do not want; and by the time you have everything to suit, you are all in a "fidget," and your customer, too, for that matter.

The platform, or floor, is made of six-inch fencing-boards, one inch thick, planed off on one side, and are two layers, running crosswise, and nailed firmly together. It is five feet square, with the four corners cut off and set on common bedstead castors three inches from the edge on each side. Near the corner are bored four two-inch holes three feet apart, into which are put four uprights two inches square, with stanchions at the bottom; the uprights are seven feet high, and are framed together at top by pieces seven-eighths by one and a-half inch, to hold all steady; they are also braced at top and bottom, as shown in the figure.

Between the uprights on each side are two movable frames two feet ten inches by two feet three inches long; the four screens or reflectors are inserted between the uprights, and

a two-inch wood screw passes loosely through them six inches from the bottom, and screwed firmly into the upright post. Fifteen inches from the platform is the bottom frame, marked X, and four feet from floor are the two top frames marked O. In front, hung on the face of the first, are two long frames eighteen inches by six feet long, hung on common door-hinges.

The background is five by seven feet, painted as described in *Mosaics* for 1877, page 48; on top is a frame, marked 5, two feet ten inches by four feet six inches, and turned on two screws at the back, the same as side-screens, and acts as a head-screen. This screen is raised or lowered to suit with a notched stick: all the top frames are covered with thin, bleached, yard-wide muslin.

The two bottom side reflectors, which are opaque, and painted a light blue, act as reflectors to light up the shadows under the eyes, nose, chin, &c. On the two, side top and long front screen, marked 2 and O, are four green opaque curtains, that roll up the same as a common window-shade, and can be pulled down to the floor, shutting off all light from the sides. On the back corners of the four re-

flectors, marked O and X, is fastened a small band that passes over a small pulley fastened in the upright post, and at the other end is a small weight to counter-balance the weight of the frame when thrown back, and make it stay in position. In front is also a thin white curtain, marked 6, which can be pulled down three feet, or rolled entirely up. The background sets back one foot from the back part, and is fastened to a two-inch post behind, which fits in a two-inch hole bored in the platform, and turns on a pivot, so that the background can be turned freely around to or from the light, and thereby graduate it more or less, and leave room to go in to arrange the head-rest, &c., which is no small item. All the frames are made of stuff seven-eighths by one and a quarter inch wide; the whole is very light, and can be pushed or pulled about at pleasure.

Here we have a set of frames so arranged that they are reflectors, counter-reflectors, transparencies, or non-reflectors, at will, and all under control, whilst it is easily and cheaply made.

THE BRITISH ASSOCIATION.

THE forty-ninth annual meeting of the British Association for the Advancement of Science has just been held in Sheffield, under the Presidency of Professor Allman. Steadily, year by year, the photographic interest of the meetings has been diminishing, the present meeting furnishing no exception to the general declension which has prevailed for years. Photography has passed out of its infancy, when it absolutely required to be nursed by science, and has become an art industry, of little scientific interest, except in cases where it becomes a handmaid to science, or presents new phenomena for science to solve.

In its general aspects, the meeting has been a successful and interesting one, distinguished in some departments by great ability. Unlike many preceding meetings, it has not been marked by theological antagonisms. The eloquent and profound inaugural address of the President was distinguished by reverential modesty when he approached those limits beyond which biological science cannot pass. An admirable sermon was preached to the Association by the Archbishop of York, himself an ardent scientific student and skilful photographer. The lectures were eloquent and interesting, that by Mr. Crookes, on Radiant Matter, especially so. The after dinner speeches were better than usual.

The first glimpse of photographic interest was displayed in Section B, Mathematical and Physical Science, when Dr. Janssen read a brief paper on the Actinic Distribution of the Solar Spectrum. He alluded to his discovery that the photographic solar spectrum possesses a maximum of intensity like the optical or luminous spectrum. This actinic maximum was near the line G, while the luminous maximum was near D. It occupied sensibly the same position for nearly all photographic substances and for lenses of different material. The time of exposure was graduated from five minutes to a small fraction of a second. By this means results were obtained which practically afforded a chronometric analysis of the spectrum. They had a bearing on the vexed question of solar oxygen, and they led practically to improvements of importance in the construction of photographic apparatus. That visual and actinic intensity are not absolutely coincident was, of course, well known, and the Professor's address, delivered in the French language, naturally did not evoke much controversy. On a subsequent occasion Dr. Janssen gave particulars of his labours at Meudon in the application of photography to the solar system, and submitted, for the inspection of the Section, glasses on which the spots of the sun had been photographed. Regarding some other trifling matters of photographic interest we hope to say something next week.

At the *conversazione* in Cutlers' Hall, amongst the objects of scientific interest exhibited were microscopic photographs by Mr. Bolton, of Birmingham. In a smaller room Mr. Bolton practically explained a new process for copying pen-and-ink writing or drawings. This process has some resemblance to lithographic and chromographic printing. On a slate coated with gelatine, and soaked in bichromate of potash, the writing or sketch is laid, which eats itself into the gelatine through the action of the iron in the ink. From this any number of copies can be made, a fresh supply of ink being alone required for each impression. By a further amplification of the process, photographs can be copied, which, to the naked eye, appear equal to the originals, and are not injured by sunlight.

Professor Ramsay was announced as the President-elect for the the next year, and he is to preside at the meeting at Swansea, which has been fixed for the 25th of August, 1880.

PHOTOGRAPHY IN NATURAL COLOURS.

THE vitality of a fallacy is marvellous. We have just been reading a chapter of photographic history written in the year 1850, in which we find the following statement. "Mr. L. L. Hill, of the State of New York, has announced to the world that he has discovered a method of taking pictures in natural colours with all the perfection of nature herself," and that he would be ready in two months to publish details. The process was, he said, more easy and certain, and the exposure shorter, than in the process of Daguerreotype then in use; and, moreover, there was to be immunity from fading. Nearly thirty years have elapsed, but Mr. Hill's method has never been published. Innumerable similar announcements have since been made, which, like the first, have proved to be fallacies or falsehoods. The interest of the intelligent public in such a thing is, however, still unabated, and we read two paragraphs in some notes on the current progress of science, in an old favourite of the public, and always well informed magazine, *Chambers' Journal*, describing what are regarded as recent steps towards photography in colours. The recent experiments of Captain Abney, described in a paper read before the Royal Society, in obtaining images of the solar spectrum in colours, are mentioned, and also the chromo-photo-collographs of Herr Albert. The writer in *Chambers* says:—

"It would be a triumph of optics and chemistry if photographs could be made to represent the natural colours of objects. Attempts towards this result have hitherto ended for the most part in disappointment. But Captain Abney, in a short paper 'On the Production of Coloured Spectra by Light,' read before the Royal Society, makes known that he has succeeded in producing approximately in the natural colours, pictures of the solar spectrum on silver plates, and also, but less brilliant, on compounds of silver held in place by collodion. 'I reserve for the present,' he writes, 'the exact details of the production of these pictures, but may say that they are produced by oxidation of silver compounds when placed in the spectrum; an exposure of two minutes being amply sufficient with a wide slit to impress the colours. The colouring matter seems to be due to a mixture of two different sizes of molecules of the same chemical composition, one of which absorbs at the blue end, and the other at the red end of the spectrum, and the sizes of these molecules are unalterable while exposed to the same wave lengths as those by which they were produced.' And he is of opinion that 'the colours may be preserved unchanged when exposed to ordinary daylight.' From this it will be understood that Captain Abney has made a step in advance of high importance."

We should be very sorry indeed to appear to underrate the work of Captain Abney in this direction; but, unless

our memory misleads us, M. Becquerel obtained an image of the solar spectrum in natural colours early in 1849. Niepce Victor and others have since secured still greater results. On a film of sub-chloride we ourselves have obtained very approximate natural colours. But in all these cases the colours were evanescent. Captain Abney is of opinion that his colours will remain unchanged when exposed to ordinary daylight. This is a decided step in advance. Our own results were gradually destroyed by daylight. We shall look for further details of our friend Captain Abney's operations with interest.

The writer in *Chambers'* proceeds to refer to the interesting experiments of Herr Albert in printing coloured photo-collographs, which have, however, no connection with photography in natural colours. He says:—

"In connection with this we mention improvements in colour-printing by which Herr Albert, court photographer at Munich, produces chromo-photographs of surprising excellence. The process commences by the taking of three photographs, each being exposed to the action of different and definite portions of the spectrum. This is effected by causing the light, before it reaches the sensitized plate, to pass through coloured glasses, or suitable coloured liquids, and, moreover, by employing in each case special solutions for the development of each negative. A positive printing plate (a glass plate gelatinized) is then produced for each negative; and, if the absorbing media and the developing preparations have been correctly chosen, it is only necessary to colour one of these plates with red, another with yellow, and the third with blue, in order, by successive printings, to obtain a picture which exhibits more or less resemblance to the original. Success appears to depend on the skill and nicety with which the absorbing materials are employed, for mixtures of colours and of colouring materials are quite different things; and, to quote the technical description, 'for the negative belonging to the blue plate we must employ such absorbing media and preparations as will prevent green from producing any influence on it, and at the same time will render blue and violet quite inactive, inasmuch as these tints must appear only on the positive plate.'

"Specimens of landscapes and of decorative panels printed by Herr Albert's process were exhibited at scientific receptions in London during the past session, and were deservedly admired. The details were shown: a plain yellow picture; then on the yellow a blue, and on the blue a red; and with these three the effect of a well-finished water-colour drawing was produced."

IDENTIFICATION BY PHOTOGRAPHY.

THE passion for justice, which is happily one of the distinguishing characteristics of man in a state of Christian civilization, has led a large number of persons believing in the legitimacy of the claims to the Tichborne baronetcy of the claimant now in Portsea convict prison to devise various methods of proving his identity. Amongst these is a very ingenious application of photography. It appears to be an ascertained fact that however much the general aspect of the human face may change during the years which elapse between early manhood and old age, the bony structure remains unaltered, and is the same at fifty as it was at twenty. This being so, two photographs taken, one at each period, would coalesce in the stereoscope, and in a little instrument invented for such tests, called the *identiscope*. This test has been applied to such photographs of the portraits of the alleged Roger Tichborne as are accessible—the Chili Daguerreotypes and a portrait taken by Messrs. Maull in 1873. The result is very remarkable in its suggestion of identity between the youthful and the matured face. To test this question more fully and with more precision, and to make other tests, a number of the gentlemen to whom we have referred,

forming the "Bristol Tichborne Science Test Committee," have appealed to the Secretary of State for permission to obtain special photographs of the Claimant, and to have copies of the Daguerreotypes now in custody of the High Court of Judicature. As might have been expected, evasion or a civil refusal is the only reply. The things are tied up with red tape, and cannot be easily untied. Moreover, if the enthusiastic gentlemen forming this committee should by chance prove beyond a reasonable doubt that the Claimant was the Baronet, and that there had been a serious miscarriage of justice, think how seriously embarrassing that would be! The Claimant was adjudged to be Orton by the decision of a British jury, and how could they possibly be in error? This is a question, however, with which we, happily, have no concern in these pages. Our aim is simply to record the interesting applications of photography. We make the following extracts from a circular issued, giving the correspondence between the Science Test Committee and the Home Secretary and other authorities:—

"It is alleged by this Committee that by a system of geometrical measurement of photographs it can be proved that, however much the appearance of a man's face may change, the bony fabrics of the features remain precisely the same at the age of forty or fifty as they were at twenty. The iris of the eye being taken as the factor of admeasurement, and horizontal lines drawn across the face, first through the centre of both eyes and then, above and below, as many lines as there are diameters of the iris, the disparity between different faces is very remarkable, for while, for instance, there are 8 diameters on Prince Leopold, there are 15 on Napoleon III; the one having large eyes and a short face, the other small eyes and long face. It is obvious that the lines on two such faces, or on any two other faces where the least difference in the size of the iris or length of the face is found, would never correspond. An instrument called an 'Identiscope' has been invented; it is like the stiff covers of a book, inside of which are placed two life size photos, having these horizontal lines accurately drawn across them. By means of a sheet of glass forming the single leaf in the book covers, these portraits are reflected one upon the other; if they represent the same person, the lines exactly fall on each other and every feature correctly corresponds; but if the portraits are of different persons they cannot match, as the slightest difference would be at once perceptible. Such a discovery, even apart from the Tichborne case, is invaluable for the detection and identification of criminals and others. By this mode of admeasurement and reflection it is found that the Chili Daguerreotype of young Roger Tichborne, taken in 1854, exactly corresponds in the minutest particulars with the portrait of the Claimant, taken by Messrs. Maull, of Piccadilly, in 1873.

"But this is not all. Photography has brought out a still more marvellous discovery which proves the Claimant's identity beyond all question.

"In early life young Roger Tichborne had certain ornate designs traced upon his face—these very same designs now appear on the face of the Claimant, though probably unknown to and forgotten by him! Little did the artist (doubtless a Roman Catholic lady) imagine, when imprinting on the child face of little Roger Tichborne forty years or more ago, that photography would in 1878-9 develop the work, and infallibly prove that its owner was a prisoner unjustly deprived of his liberty, his property, his title, and his rank, a prisoner in a convict cell, working out a double sentence of penal servitude, the result of a refined rendering of the law, disgraceful to the legal minds who designed and tyrannically enforced it with fines and imprisonment on those who uttered a word of protest, and humbling and disastrous to the nation that permitted it. The real Sir Roger Tichborne as sentenced to seven years' penal servitude for swearing he is not Orton, which no one now believes him to be, and seven more for swearing he was Sir Roger Tichborne, which he certainly is, and both sentences the Home

Secretary now declares he shall fully endure. Such may be his determination, but the nation will have something to say at the next election. Even though our national pride be brought down and Royalty itself be humbled—for unfortunately our Queen (whose ready sympathy we have all admired) has gone beyond the limits of discretion—Justice, more sacred than the claims of party, must be vindicated at any cost. The voice of true Christian patriotism cannot be stifled, even though chaos may ensue.”

PRODUCING PHOTO-MECHANICAL PRINTING PLATES.

M. BOIVIN describes a simple method of producing plates for printing after the Woodbury method. It does not seem likely to produce the highest delicacy possible, but is very simple. He first produces a good carbon print, and then hardens the image of gelatine by means of alum or bichloride of mercury, and dries it, when it will be free from dust. Next, he says (we quote his article in the *Moniteur*):—

“When I wish to obtain a photoglyphic mould, I wash the image formed of hollows and reliefs, with soapy water (eau de savon), afterwards I cover it with fine plaster of Paris. The mould, obtained with purity, is dried and steamed, and can in these conditions serve for the printing in coloured gelatine. For obtaining the proof we pour upon the surface of the mould a little of the coloured gelatine, either black or any other colour; we place above it a leaf of ordinary paper, or, which is better, coagulated albumen paper; after, we place upon all a thick glass upon which we put a weight sufficient to insure the adherence. In a little time, when the gelatine has set, we raise the leaf of paper, which carries with it the image which remains adherent; for giving to it more of solidity, and to fix it, we pass it through alum, as we do proofs in carbon, after which we finish as usual. If we desire to obtain a mould in metal, it is very easily done with the metal of Darcet (fusible alloy), which is very fusible.”

We may remark here that D'Arcet's fusible metal consists of—

Bismuth	8 parts
Lead	5 ”
Tin	3 ”

It melts below the heat of boiling water. It may be useful to add here some other forms of fusible metal for the use of the experimentalist in this direction. They possess great advantage in having low melting points. Walker's fusible metal consists of—

Bismuth	8 parts
Tin	4 ”
Lead	5 ”
Antimony	1 part

The metals should be repeatedly melted and poured into drops, until they can be well mixed previous to fusing them together. Onion's:—

Lead	3 parts
Tin	2 ”
Bismuth	5 ”

Melts at 197° F. If to the latter, after removing it from the fire, one part of warm quicksilver be added, it will remain liquid at 170° F., and become a firm solid only at 140° F. Another—

Bismuth	2 parts
Lead	5 ”
Tin	3 ”

Melts in boiling water.

Some of these are used to make toy spoons to surprise children by their melting in hot liquors. A little mercury (as in 4) may be added to lower their melting points. D'Arcet's and Walker's are specially adapted for making electrotype moulds, French cliché mounts are generally made with the alloy of Walker. These alloys are also used to form pencils for writing, also as metal baths in the laboratory, or for soft soldering joints. No. 4 is also used for anatomical injections.

Higher temperatures, for metal baths in laboratories, may be obtained by the following mixtures:

1 part tin and 2 parts lead melt at 441.5° F. 1 part tin and 1 part lead melt at 371.7° F. 2 parts tin and 1 part lead melt at 340° F. 63 parts tin and 37 parts lead melt at 344.7° F.

Returning to M. Boivin, he says:—

“We take the mould in plaster after drying. We do not stearine it, but we carry it by a gentle heat in a stove and immediately apply it upon the metal in fusion, as this is practised in the process of moulding employed in galvanoplasty.

“Moulds in metal have over moulds in plaster this advantage, that with them we can print an indefinite number of proofs, without having to fear the least alteration, which is not the case with plaster, which is very fragile.

“It goes without saying that this photoglyphic process, so simple, can as well be employed for the reliefs produced by the aid of the actual carbon process, with sensitizing by the bichromate of potash.

“The important point of departure is having a good proof formed of hollows and ridges, before the moulding: whichever process be employed for obtaining it, we shall attain the same end.”

PHOTOGRAPHY AS APPLIED TO THE REPRODUCTION OF PLANS AND DRAWINGS.

BY DAVID TOWNSEND, B.S.*

IRON.—Next in importance to the salts of silver come those of iron, and their reactions furnish us with numerous methods for reproducing drawings. The compounds of iron most used are certain double salts, such as citrate of iron and ammonia, oxalate of iron and potassium, tartrate of iron and ammonium, and, of the single salts, the oxalate and per-chloride. In every case the iron must be in the ferric state, otherwise no reduction will occur, and consequently no picture will be produced. All the processes depend upon the reactions of ferro- and ferri-cyanide of potassium on the salts of iron, as already explained. The only thing we have to consider, then, in choosing a salt for a sensitizer is, which one will be the most sensitive to light, and can be procured cheapest. There are two processes which may be considered as typical, the first being called—

Pellet's Process.—This was invented by H. Pellet, of Paris, and is quite recent. It gives a blue picture on a white ground, the operations being as follows.

The best quality of paper must be used, or the perchloride of iron which is used to sensitize it will soak through, making very ugly spots on the back when developed. If the paper is not sufficiently glazed, liquid gum or gelatine should be added to the sensitizing bath. I obtained the best results in my experiments by using albumenized paper such as is used in portrait photography. The paper is cut to suit the drawing, which for this process must be on tracing cloth, and is then sensitized by floating it, as before described, on a bath composed of

Perchloride of iron	10 parts
Water	100 ”
Citric or tartaric acid	5 ”

* Continued from page 387.

The sensitizing must be performed in the dark room, and the solution always excluded from the light. The paper is allowed to remain on the bath for thirty seconds, when it is carefully removed and hung in a warm place to dry. It can then be used immediately, or preserved unchanged in a dark place. The tracing to be copied is placed in a printing frame together with a sensitive sheet of paper, and is then taken into the light. In sunlight, from fifteen to forty seconds will be sufficient to reduce all the iron to the state of proto-chloride, except such parts as are protected by the black lines, which will still remain in the ferric state. If the day be cloudy, from fifteen to twenty minutes will be necessary to complete the reduction. The time of exposure can be determined by a few experiments, as it will vary considerably with the time of year, the light being twice as strong in summer as in winter. When the exposure is complete, the frame is brought back into the dark room and opened, when a faint image will be observed on a deep orange-yellow ground. The paper is now plunged into a bath containing

Yellow prussiate of potash (K_4FeCy_6)	24 parts
Water	100 ,,

when a blue image will appear on a white or bluish ground, if the development is sufficiently prolonged. The parts protected by the black lines, being still in the ferric state, will be precipitated by the ferrocyanide as prussian blue [$Fe_4(FeCy_6)_3$] while the unprotected parts, being reduced to the ferrous state, will form a white precipitate which absorbs oxygen from the air, and speedily turns blue if not removed. If the exposure has been too short, all the perchloride will not be reduced, and blue spots will appear on the ground; but if too long, the image itself will be somewhat faint, owing to a partial reduction under the lines, and will require an exceedingly long development. When the image is sufficiently developed, the print is removed and washed in an abundance of clean water, to remove the white precipitate, after which it is put for a few minutes in a bath of

Hydrochloric acid	1 part
Water... ..	10 parts

which will deepen the blue picture and whiten the background. After washing for some time, the prints can be dried, and are then finished. This process is hardly applicable on a large scale, as it requires such care and nicety of execution to attain desirable results that it could not be trusted to any but experienced hands. If the paper, after exposure, had been put in a bath of

Red prussiate of potash ($K_6Fe_2Cy_{12}$)...	25 parts
Water	100 ,,

a reversed picture would have been obtained, having white lines on a blue ground, owing to the fact that the unprotected parts, being reduced to the ferrous state, would be precipitated by the ferricyanide as Turnbull's blue ($Fe_3Fe_2Cy_{12}$), while the protected lines would remain unchanged, so that when washed in water the perchloride would be dissolved, giving white lines on a blue ground, which would be further intensified by the acid bath. The name of cyanotype was given to the latter process by its discoverer, Sir John Herschel. He also developed on a dilute neutral solution of gold tri-chloride, getting a purple picture, to which he gave the name of chryso-type. Any other persalt of iron could be used as a sensitizer, and developed on the ferrocyanide bath with the same result.

Blue Process.—The process which is most used in America, and which has been largely adopted by our manufacturers, is known as the blue process. The drawings are reproduced in white lines on a blue ground, and I understand the paper is sold in the market already sensitized, although it can be prepared cheaper and just as well as the

bought article. Almost any heavy well-glazed printing paper will answer the purpose, but, as this is the only expense, a good quality should be used. The sensitizing bath consists of

a.—Citrate of iron and ammonia ...	1 part
Clear water	4 parts
b.—Red prussiate of potash	1 part
Water	6 parts

The two solutions are dissolved separately, and preferably at the ordinary temperature; when in complete solution they are mixed, and kept in a yellow bottle, or carefully excluded from the light, which would cause a blue precipitate. If the paper is not sufficiently sized, gum or gelatine should be added to give it body and prevent the liquid from soaking through. The sensitizing is performed as follows, in non-actinic light:—The sheet of paper, cut to the required size, is pinned to a clean board; some of the solution is poured into a vessel, and the paper painted with it by means of a soft camel's hair brush three inches wide. The brush is dipped into the solution, and the paper completely moistened in one direction; then, without removing the liquid, it is smoothed until no streaks or lines appear. Some prefer to use a sponge, but this causes uneven spots, and mars the beauty of the picture. In this way a very little solution will cover quite a large surface. Before putting the brush away it must be carefully cleaned. The paper is unpinned, hung upon a line, and when dry will keep a long time in the dark. It should be a brass-yellow colour when rightly prepared. To make a copy, the drawing, on tracing cloth, is put into the printing frame, as usual, with a sensitive sheet, and exposed to sunlight for six to ten minutes, or to diffused light for one to two hours. The double salt is reduced to the ferrous state where the light strikes it, and immediately combines with the red prussiate present, to form Turnbull's blue, while the protected parts remain unchanged. The exposure should be continued, until, on opening the frame, the white lines have almost disappeared and the background is greyish-green.

The sheet may also be exposed on a board padded with flannel, over which is placed a sheet of plate glass, but this requires to be always horizontal, and needs more apparatus than it would cost to get a regular frame. When exposure is finished the print is removed, and put immediately into a tank of running water, when the lines will become white (unless over-exposed or not in contact), while the ground becomes dark blue. After sufficient washing, the ground can be improved by transferring to a bath of

Hydrochloric acid	5 parts
Water	100 parts

when it must be again thoroughly washed, and then dried. The colour always darkens on drying, and prints that would otherwise be under-exposed have very beautiful light blue ground.

This process has become the favorite one, owing to its great simplicity, and the ease with which any one can work it; the objections to it are, the length of exposure, especially on cloudy days, and the impossibility of copying drawings from anything but tracing cloth or paper. In very large sheets the fine lines are apt to be reduced, thus making the picture somewhat uncertain in parts. If, instead of mixing the solution, the paper had been sensitized with the citrate bath and then exposed, the reduction would have been very rapid (fifteen or thirty seconds), as this is the most sensitive salt of iron. The picture could then be developed in the ferricyanide bath, and finished as described; but in this case it is better to sacrifice sensitiveness to convenience. The other double salts could be used to replace the citrate, but they require a longer exposure.

Correspondence.

PERMANENCE OF GELATINE NEGATIVES.

A SUGGESTION.

DEAR SIR,—Now that the permanency of gelatine negatives is justly doubted, would it not be worth while for some one of leisure to experiment with bichromate of potash? Say, after fixing the negative, soak in a weak solution of bichromate, and expose to sunlight if possible, so as to convert the film into an insoluble varnish. Alum is of little use, except to prevent frilling, as the film will swell when damp, even after long soaking in it.

A. E. BANNISTER.

Bernard Street, Southampton.

COPYRIGHT AND CHEAP COPYING COMPANIES.

DEAR SIR,—If I read the new Copyright Act and your article on it correctly, photographers will not in future be robbed of their orders for reprints by those generous patrons who get a few cartes taken at some good studio, and then send one to some (so-called) photographic company to have it copied (I had almost written caricatured) at 2s. 8d. per dozen, which will be to most artists a source of congratulation.

By-the-bye. If the News was in less able hands, one might be tempted to remind your "Gup" correspondent that gossip, scandal, and slander often reside in the same street, and in these days of "terraces" one is often mistaken for the other, until unpleasantly reminded of the error.

"Gup," or gossip, is generally unwholesome, almost always personal, and sure to give offence to somebody sooner or later; and in a somewhat large experience I never yet remember any periodical being increased in value by devoting a column to it. However, I have no doubt the Editor of the NEWS will take good care (both for his own sake and his readers') to draw the line at the right place.—Yours truly,

F. A. BRIDGE.

Dalston, August 27.

EMPLOYERS AND EMPLOYED.

SIR,—“Mass,” in his letter of August 1st, mentions an employer in Bath who had him in the same way as the Exeter man had Mr. Bradforde. I am sorry to say I have fallen into hands similar to those described by both. At a moment's notice this man (no photographer himself) has turned me out after bearing patiently his abuse for over twelve months, his only excuse being that I had been with him too long. I have now determined to follow Mr. George Bradforde's example in joining the Photographers' Benevolent Society, and trust my fellow-workmen will do likewise; they will then be protected from such fellows as the above-mentioned employers, and get situations in good places of business where they will be treated well, not as I have been, by a man who hasn't a soul above toys.—I am, &c.,

QUICK SILVER.

Proceedings of Societies.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

At the last meeting, President NEWTON in the chair, the minutes of last meeting were read by the SECRETARY and approved.

Mr. THOMAS exhibited to the Section a large number of prints by Mr. Willis's permanent platinum process, as purchased by the British Government for the Home and Foreign Offices. The life-size pictures were printed in sixteen or twenty minutes, and their price is about \$3 25c. each. They are all

made from small negatives by both direct and reflecting cameras. There is no special paper necessary for the process. The image can be seen during the printing, so that there is no danger of being unable to control the exposure. The process takes about one-third of the exposure of the silver process. The picture is so permanent in the paper that it is not destroyed or faded by any chemical action which will not injure the paper or platinum, like hot aqua regia.

Mr. MASON. The pictures exhibited by Mr. Thomas are certainly very remarkable ones, and are of a class in which we have very few exhibits. I don't remember more than two or three occasions in the last ten years on which we have had solar prints exhibited. I suppose one reason has been that the ordinary solar work has certain imperfections which we don't see in this, viz., that the paper is not as white, and that the delicacy of light and shade in the negative is not represented in print as it is in these. In this life-size picture of a gentleman, the texture of the lace and around the neck is preserved in a way I never saw before on a large print; it lacks that muddy appearance which we usually find. From the process used, we have every reason to believe it is better than the silver in many respects, and, as Mr. Thomas says he can print them faster, and as the expense is about the same as for silver, it shows an advance in that class of work.

Dr. VANDERWEYDE asked if platinum salt had been used in the collodion process. It is more sensitive than silver.

Mr. THOMAS. The platinum in this process plays no part at all in sensitiveness. The picture is printed in iron. The platinum lies by the side of the iron, and has no connection with it. The platinum is in solution on the paper with the iron salt, and when that ferric oxalate is exposed to light it turns to a ferrous oxalate, and the moment the ferrous oxalate is brought into contact with oxalate of potash, the platinum is precipitated in a metallic state. It only precipitates wherever the iron salt is turned into the ferrous oxalate by the action of light.

Dr. VANDERWEYDE. The silver salt in paper is essentially the same as we use it in collodion. It is the reduction of the silver which makes the picture. My question is, whether the platinum will do in the place of silver?

Mr. THOMAS. These prints do not require half the work in finishing that silver prints do. The deep shadows are not clogged up at all.

Mr. CHAPMAN. It seems to me that instead of putting platinum salts into collodion, gelatine would be better. I don't now really recall to mind any method by which iron can be kept in a solution which will dissolve gun-cotton. Here the iron has to be kept in solution, and the platinum in solution, and they are both in the same vehicle—that is, in the paper—and they do not act upon each other at all until after the exposure to light. The iron is turned into ferrous oxalate; then the development is done with the oxalate of potash. The oxalate of potash then connects these two and precipitates the platinum. These two salts might be kept, perhaps, in a film of gelatine.

Dr. VANDERWEYDE. The suggestion is to use the platinum like one does the silver.

Mr. CHAPMAN. The iron in this case must be converted into a ferrous oxalate, or it will not precipitate the platinum. Iodides and bromides of platinum have been tried instead of silver, but they are not as sensitive by any means as silver. It is necessary to have the iron there present, so that the light may act upon it and convert it into a ferrous oxalate from a ferric. Then the two are lying side by side, but not united until the potash comes and unites the two and precipitates the platinum as a metal.

Mr. NEWTON. The trouble in working the collodion would be to get the ferrous oxalate in solution. It is not soluble in water; it is soluble in a solution of oxalate of potash. You could not dissolve iron in ether or alcohol. The ferrous oxalate is not soluble in water, and it would not be in a solution of gelatine and water, or albumen.

Mr. ROCHE exhibited to the Section some printing on wood blocks for engravers, and stated that he had published the process in *Anthony's Bulletin* as early as 1873 or 1874. He also exhibited an ordinary box-wood block having upon it a photograph from which prints in ink were taken without having been engraved.

Dr. VANDERWEYDE, referring to Mr. Chapman's remarks at the last meeting about the different coloured glasses used in his spectrum examination, said that he found the aniline colours to be most perfect, and stated the result of his experiments

with aniline and other colours in the spectrum investigations made by him.

Mr. MASON asked whether his experiments with aniline colours had been of a nature which admitted of his stating that he considered any of them permanent.

Dr. VANDERWEYDE. They keep very well; better than permanganate of potash. The least organic matter in the water used in the experiments will change the tint; but aniline colours as a whole, I find, keep very well. We all know that aniline colours in dyeing are permanent, if used with the proper mordant.

Mr. NEWTON. The red and the orange are very permanent, but it makes a difference with many colours what vehicle is used to carry them; indigo in oil is not permanent, whereas in water it is considered a permanent colour. Aniline has been incorporated with collodion as a vehicle, and I have some of it that has been in my dark-room window for six years, not exposed, however, to direct sunlight. I have not observed that it has changed. This collodion was brought from Bahia, South America. I therefore consider this orange and scarlet aniline incorporated with collodion as permanent.

Mr. ROCHE exhibited to the Section the lantern furnished by the Messrs. Anthony, and a discussion on lanterns followed, after which the proceedings terminated.

Talk in the Studio.

BLISTERS.—A correspondent of *Anthony's Bulletin* writes:—"It seems to me that the use of muriatic acid upon the back of albumen paper has advantages which, if once tried, would never be omitted. The prints are certainly more brilliant, print quicker, and the tones are better, whilst blisters are unknown. My plan, which I think is new, is to first silver the paper, drawing the same over a glass rod to take off the excess of silver, and prevent any drip; then, while still wet, to immediately float the back of the paper on the acid bath of the strength you advise, namely, one hundred ounces of water to one ounce of acid. All that is required is to be careful not to let the solution run over on the silver side. I prepare whole sheets, and have no trouble."

PHOTOGRAPHIC PATTERNS.—"One of the silk manufacturing firms of Lyons, France," says the *Scientific American*, "are introducing the production of photographic impressions on stuffs. They sent to a recent meeting of the Photographic Society several pieces of silk with a variety of photographic pictures printed thereon, including, among others, a number of large medallions representing pictures of the old masters. The length of the specimens thus exhibited is stated as being no less than 131 feet. The process by which they are produced is not given, but it is believed, says the *Commercial Bulletin*, that the prints are made with salts of silver."

CARBON PHOTO PRINTING.—The same journal informs its readers that "Mr. F. Gutekunst, 712, Arch Street, Philadelphia, has organized a complete establishment for the printing of photographs by the carbon process, that is, in printer's ink that never fades. We have received some specimens of the work done, which are unsurpassed for excellence, and reflect credit on the printer. For book illustration and portraiture, this method of printing yields the finest results."

TO KEEP A PLATE WITHOUT STAINS DURING A LONG EXPOSURE.—Every photographer is familiar with the risks of stains from partial drying of the plate when a long time elapses between exciting and developing the plate. Here is a method whose extreme simplicity will entitle it at least to a trial, and one trial will prove its utility. The plan is simply to flood the plate with a few drachms of distilled water previous to exposure; the water is then poured from the plate to a developing-glass, and must on no account be thrown away, for in this appears to lie the secret of success. After exposure the plate is again flooded with the same water that was previously used, and which, after thoroughly moistening the film, is again returned to the developing-glass, and mixed with the required quantity of developer, and the development proceeded with as usual. Plates so treated will give pictures as clear and free from markings as if only exposed in the camera for a few seconds.

HOW TO SUN A BATH.—The following method is far better than the old way of sunning in a clear glass bottle, as it saves much time. Having neutralized the bath with carbonate of soda, or otherwise, place it in a large, flat, white porcelain dish. After a few hours a black scum will appear on the surface; this is removed by means of strips of blotting-paper, and the light is once more free to act on the solution in an unobstructed manner. The bath should be skimmed every few hours until it is found to remain permanently clear, or nearly so, when it is ready to be filtered and to have its strength diluted by the addition of water, for, as will readily be perceived, an exposure in a flat dish, such as that to which the bath has been subjected, necessarily causes a considerable quantity of the water to evaporate, carrying with it much of the ether and alcohol. After being diluted to the proper degree of strength the bath is filtered, and acidified, if necessary, when it will be found to work as well as ever it did, free from streaks, stains, and pinholes.

PHOTOGRAPHIC TRANSIT MEASUREMENTS.—M. Cornu has been investigating the best theoretical conditions for measuring the photographs of the transit of Venus, with especial reference to the micrometric determination of angular distances. From Mouchez's photographs he deduces a value, for the sum of the radii of the sun and Venus, which differs from the value in the *Connaissance des Temps* by less than $\frac{1}{3}$ of 1 per cent. This indicates a possibility of determining the sun's distance, by photographic observations, within $\frac{1}{10}$ of 1 per cent., or within less than 100,000 miles.—*Comptes Rendus*.

DISADVANTAGES OF PHOTOGRAPHY.—"A friend of mine," says a writer in *Truth*, "who has just returned from Egypt, tells me that the doukey-boys of Cairo call their quadrupeds by the names not only of our eminent men, but of the fashionable beauties whose photographs adorn our shop-windows. He successively gave a trial to Mrs. Langtry, Lady Lonsdale, Mrs. Wheeler, and Mrs. Coruwallis West. The first he found very lazy, the second had a disagreeable habit of rolling in the sand, the third walked well, but trotted unevenly, whilst the fourth was skittish, and threw her head up in the air in a jerky manner. Then he hired Sir Stafford Northcote; but this beast, although sure-footed, was slow in his movements; and, after riding several other of our statesmen, he fell back upon the Bishop of London, whom he describes as a very serviceable jackass. But my friend, who is a very fervent member of the Church of England, was much pained by the boy to whom the Bishop belonged frequently beating him with a heavy stick and continuously addressing him as a 'devil.'"

PHOTOGRAPHIC ILLUSTRATION OF MENTAL OPERATIONS.—In one of the excellent series of "Men of Letters," published by Macmillan and Co., Professor Huxley illustrates his argument respecting complex impressions which are more or less different from each other by reference to composite portraiture, thus:—"This mental operation may be rendered comprehensible by considering what takes place in the formation of compound photographs—when the images of the faces of six sitters, for example, are each received on the same photographic plate for one-sixth the time requisite to take one portrait. The final result is that all those points in which the six faces agree are brought out strongly, while all those in which they differ are left vague; and thus what may be termed a *generic* portrait of the six, in contradistinction to the specific portrait of anyone, is produced."

TWO NEW METALS.—A correspondent writes:—"The discovery of two new metals is announced, named Samarium and Norwegium. Paradoxical as it may sound to speak of the finding and christening of a hitherto unknown metal before it has been either seen or handled, yet such is the case with Samarium. As happened in the instance of the metal gallium, it has first become known to science by means of the spectrum analysis alone; nor can it be doubted that in the verification of its existence by the senses it will in due time follow the same precedent. It is well known that by means of the characteristic rays which are seen in the luminous spectrum produced by the combustion of any substance, it is possible to single out the known or unknown bodies which enter into the combination. As are the rays, such are the elements producing them. When rays are found answering to no substance already catalogued, the existence of some new body is naturally inferred from the fact. That was how gallium was first brought to light, and now we have a like history for Samarium. M. Lecq de

Boisbaudran, who has greatly distinguished himself by his researches in this branch of science, found, as he was examining a mineral known under the name of Samarkito, an emission of unfamiliar rays. He has inferred thence the existence in this mineral of a new metal which he has accordingly named Samarium, and all he has now to do is to isolate it from the other elements with which it is as yet combined. This has already been done for the other new metal, Norwegium, patriotically so named after his fatherland by its discoverer, Professor Tellef-Dahl, of the University of Norway, who detected it in a metallic compound of arsenic and nickel. The Professor has even determined the principal properties of his new metal, which he describes as being white, slightly malleable, of about the hardness of copper, and fusible at a dull red heat. Its density is represented by 9.44, and its chemical equivalent is 145."—*Times*.

HOW TO PRINT SEVERAL COPIES OF A LETTER.—A new process, by M. Chardon, is as follows: Make a zinc tray about a quarter of an inch in depth, and pour into it a warm solution made as follows:—

Water	4 ounces
Sulphate of baryta	2½ "	
Sugar	1 ounce	
Gelatine	1 "	
Glycerine	6 ounces	

Write whatever is required to be printed upon a sheet of white paper, using instead of ordinary ink the aniline colour known as "violet of methylaniline;" as soon as the writing is pretty dry, lay it upon the gelatine surface with the palm of the hand. The ink will be absorbed by the gelatinous product. All that is to be done in order to obtain a fac-simile of the writing is to lay a sheet of paper upon the writing on the gelatine and rub the back with the hand. From forty to fifty can thus be drawn off in a few minutes. We find that in warm weather plates thus prepared remain too soft and adhesive to work satisfactorily. Better results are obtained when a larger proportion of barium sulphate—say 3½ instead of 2½ ounces—are used, and the mixture is heated for an hour on the water-bath.—*Scientific American*.

To Correspondents.

GUPPY.—The simplest remedy for the sensitized paper discolouring is to keep it, after silvering, between sheets of blotting-paper which have been soaked in a solution of carbonate of soda. Some samples of albumenized paper are more liable to discolour than others, but this treatment will prove a remedy in all cases. 2. One cause of the weakness in the print enclosed is the quality of the negative, which lacks intensity to some extent, and hence does not permit of sufficiently deep printing, which is necessary to secure rich tones, whether warm or neutral. If you plunge the prints into the toning bath with little or no washing after leaving the printing-frame, you will get better results with the paper on which enclosed print is printed. 3. There is no safe local remedy for perspiring hands. Constitutional treatment under direction of a medical man may effect a cure; but any attempt at suppression by local treatment, such as the use of a solution of alum or tannin, may produce serious mischief. Frequent washing and plunging in cold water may be useful. 4. We presume that you refer to the mode of estimating the amount of silver in a solution by a standard solution of chloride of sodium. Dissolve 8½ grains of this salt (pure) in 6 ounces of distilled water. Of this solution, 2 drachms will precipitate a grain of nitrate of silver, so that the strength of a solution is easily tested.

TYRO.—A good half-plate lens will probably answer your purpose very well. It will not necessarily fit any camera; that will be governed by the solar focus of the lens. Its shortest focus will probably not be less than six or seven inches, in which case the camera must admit of being closed up to that length between the lens and ground glass. A half-plate lens is supposed to take pictures 6½ inches by 4½ inches. A camera from the establishment you name will doubtless answer. A camera simply means the camera without lens. You will find in the catalogue of the establishment you name cameras of good quality at a reasonable price.

POOR PERPLEXED PRINTER.—We gave all the details we received, and as the plan was empirical rather than theoretical, we could only guess, or test by experiment, for anything further. We should think the bath would be kept up by adding to it fresh solution made as at first.

C. W. FOLKARD.—Anthony's soluble cotton is, we believe, supplied by Mr. Atkinson, of Manchester Street, Liverpool. Incidental examinations of the kind have been made, but nothing exhaustive or systematic.

A. W. T.—Full detail, of service for working, would require more space than this column will afford; but we will, in our next, devote a column to the subject. In the meantime we may give you a tough formula. Dissolve in 1 ounce of plain collodion, of not too rough a texture, 2 grains of chloride of calcium and 2 grains of citric acid. In another ounce of plain collodion dissolve 10 grains of nitrate of silver, and mix the two lots of collodion. Coat paper or glass, and proceed as with albumenized paper printing.

W. W.—We have not tried gelatine as a substratum in such case, not having had occasion for a substratum at all. We could only ascertain, therefore, by experiment. 2. Under the circumstances you name there can be no impropriety in keeping the prints face upwards. 3. We do not see any method of obtaining the plates in question, unless they are introduced into the English market. We see no difficulty in preparing such plates, using the collodion-chloride process, but substituting gelatine for collodion. We used such a process many years ago. 4. Gelatine has been frequently used as a preliminary coating in wet and dry plate work, and many photographers prefer it. If used, the addition of a trace of carbolic acid would probably be an advantage. India-rubber has been found a good substratum. About a one-grain solution is used.

ERNEST KAVANAGH.—A saturated solution of any body is a solution containing as much of the solid substance as it will dissolve. The way to make a saturated solution of anything varies with the substance and its solvent, and also the temperature. Most salts are readily soluble in water. Resins and fatty bodies are only soluble in alcohol or benzole, or other hydrocarbons. Some substances are only soluble by the aid of other bodies like alkalies, or, indeed, of neutral salts. Bichloride of mercury is, for instance, sparingly soluble in water, but much more readily soluble if chloride of ammonia is added to the water. Most substances are more easily soluble in powder or crushed up, and many are made more soluble by the aid of heat. A good plan to make a saturated solution of many bodies consists in powdering them in a mortar and adding hot water. The solution when cold will deposit the excess dissolved when hot, and the clear liquid will be a saturated solution.

J. C. BURNOW.—We doubt very much whether a broken ebonite tray would be of any value for working up again. Our impression is that the india-rubber is vulcanized or ebonized whilst in a plastic state, and moulded to form, and, once hardened, is not easily softened again. Silver and Co., of Bishopsgate Street, are manufacturers. Hyposulphite of soda is better not kept in a state of solution. It is wise to keep the scales in good order.

B. B.—We do not know any better than the Autotype Company, Rathbone Place. We do not know of any one in the City.

W. J. BYRNE.—We regret that we have no information about the Australian Exhibition, except what we have occasionally seen in the public prints, none of the official documents having been sent to us.

JOHN B. CHAMOND.—How far ferrotypes may be successfully produced by gas-light is a matter for experiment; but we see no reason to doubt the success. Negatives on gelatine plates have been successfully produced by that light by Mr. Laws.

P. FINCHAM.—The registrations announced in our columns are simply those effected by our publisher, and serve as acknowledgments that the work is done. We make no record of registrations generally.

ENQUIRER.—We hear best accounts of No. 2; also of No. 7.

REFINER.—It would be impossible to give you efficient instructions in this column. You will find valuable articles with full information in our YEAR-BOOKS. 2. Use a warm solution of carbonate of soda.

J. J. A.—If we were in the same position, we should take those plates with which we had already succeeded. Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHERS WHO DON'T KNOW THEIR OWN BUSINESS— THREE ACIDS IN THE MANUFACTURE OF PYROXYLINE.

Photographers who don't know their own Business.—Some years ago there appeared in these columns a description of several well-known photographic establishments under the name, if we remember rightly, of "Famous Studios." Ever since that time—it may be ten or fifteen years for aught we know—a strong feeling has been in our breast to write a few chapters on infamous studios. We have not abandoned the idea even now, and one of these days—it is well to do nothing rash—the long-thought-about subject may get into the print. It is not on this matter that we are going to chat just now, at any rate, so we shall for the nonce avoid entering into a discussion upon the advantages and disadvantages of employing the fingers in place of a dipper in the plate bath, and resist the temptation of combating upon theoretical grounds the practice of wiring on the colodion film to the glass to prevent it slipping. What we propose to deal with are other shortcomings in studios that have come under personal observation, and seem to merit criticism from an outsider's point of view. We know not if the shortcomings we mention are at all widespread, but as the experience we speak of is confined to three studios only, which we have visited as bona fide customers during the past twelvemonth, it may be that our outcry is only another instance of much ado about nothing. To unburden ourselves, then, of one impression that struck us with some force when we accompanied a lady six weeks ago to make an engagement at a studio. The lady in question was no longer in the heyday of her youth, we will at once admit, but that is all the more reason why our friend the photographer should have been more circumspect. "No, you will look best taken in Rembrandt style, you will, indeed; allow me to judge, please; you will prefer it to any other, I am sure." And, to do the photographer justice, he did in the end produce a remarkably pleasing likeness with Rembrandt lighting, only he need not have been in such a hurry to propose that particular style. It was as if he had in view the lady's years, and thought that lighting the model from behind would be so much more preferable to lighting it from the front. At least, so it occurred to our companion and to ourselves; and if this was not the drift of the photographer's eager remarks, I would point out that sitters are sensitive, and a little too ready to take offence where no offence is meant. There is a popular operetta of Arthur Sullivan's called *Trial by Jury*, that is very generally known, and in one of the songs is a description of a somewhat aged young lady, of whom it is said:

"You really might take her for 43
In the dusk, with the light behind her."

These lines struck us very forcibly when it was proposed to take our lady companion "with the light behind her," and that is why we have written down the incident here. Another shortcoming we remarked in the studio was the dressing room; this time we were accompanied by two children, and being only children, it was supposed that anything like a retiring room was unnecessary. At least, it was only after a special request that we were admitted in that sanctum. The room in question was most inadequately appointed. At first sight its grandeur was most overpowering; there was a mahogany toilet table, and a magnificent mirror, but somehow it seemed to contain just the things that were not wanted, and lacked those which were necessary. But the most striking shortcoming of all was the want of business habits in two of the studios we visited. In one case our money was refused when we desired to pay on making an appointment, and in the other an elaborate receipt was given, but the portraits

themselves were afterwards forthcoming only in dribbles, and then as the result of repeated applications. Do photographers, as a rule, keep books, we should like to know, and do they carry on business as business men should? We ourselves were once seriously thinking about embarking in a photographic enterprise; it was after a visit paid some ten years ago to M. Reutlinger's famous studio in Paris. There was a little recess or bureau leading out of the reception room, and while we were looking at specimens, there was a constant flow of visitors into this little sanctum. They staid but a short time; each put down one or more gold pieces, received a ticket in exchange, and went their way. It was very pleasant to see this. Matters were arranged as quickly and deftly as at the box-office of a theatre, and money rattled in almost as quickly. The scene had an inexpressible charm to us, we remember, and thus it was that the thought occurred to us of embarking upon a similar calling. In the studio, as we afterwards saw—a small strip of a studio at the top of one of the big houses on the Boulevards—matters were managed quite as orderly; and as the sitters one after the other kept their appointments and departments, an accurate entry was made of details, and the date specified on which their order would be finally executed. No wonder M. Reutlinger, with good photography and good business habits combined, managed to thrive so well, and no wonder, too, that photographers who have no idea what system and punctuality mean, are perfectly incompetent to conduct a business and make both ends meet. "You pay afterwards when your portrait has been taken," said a young lady to us the other day, returning our sovereign. "Pay afterwards?" was our exclamation. "Yes sir, that is our system," said the young lady precisely. "Well, our name is Driveller, and you may give Mr. Kammerer my compliments and tell him his system is a very bad one." How can an intending sitter have any respect for an establishment in these circumstances? We felt inclined to walk about and whistle, take up the specimen cases and laugh at every pose we saw. The work lost every bit of its value in our eyes, and we fingered the elegant porcelain cups, with their pretty portraits, with as much veneration as if they had been mugs "for a good Boy" at a fancy bazaar. If a photographer wishes to impress the public with a sense of his proper importance, he must never fail to make prepayment compulsory.

Three Acids in the Manufacture of Pyroxyline.—Some experiments are being made in this country with pyroxyline prepared by the action of three acids: hydrochloric, nitric, and sulphuric. Aimé Girard, we believe, has already manufactured gun-cotton in this way for some time past, and has made a thorough investigation of the products. Of course there is no novelty in acting upon cotton or cellulose with hydrochloric acid. Chemists resort to the operation frequently for the purpose of securing pure cellulose. The cotton acted upon by hydrochloric acid is rendered into a fine state of division, and most of its impurities are thereby removed. But it is contended now that this hydrochlorised cellulose is something more than cellulose in a pure condition, and that when subsequently treated with nitric and sulphuric acid to turn it into nitro-cellulose or gun-cotton, it has different qualities to those possessed by pyroxyline as ordinarily manufactured. How far this is correct, and how far it will affect photographic gun-cotton, are matters which chemists must determine for us.

FRENCH CORRESPONDENCE.

THE MONUMENT OF DAGUERRE AT CORNAILLES-EN-PARISIS —A MAGISTRATE'S OPINION OF THE INTELLIGENCE OF PHOTOGRAPHERS.

The Monument of Daguerre at Cornailles-en-Parisis.—The project to erect a monument in memory of Daguerre has made considerable way of late, and as the question has

now entered on a practical phase, we may assume that it is definitely settled. As I have already informed the readers of the PHOTOGRAPHIC NEWS (see number for 13th of June, page 284), in consequence of the attack on the memory of Daguerre made by the committee appointed to raise a subscription for a memorial of Nicéphore Niepce at Châlons-sur-Saône, the members of the Photographic Union of France determined to apply to the municipality of Daguerre's birthplace. The object of this application was to induce the municipal authorities of Cormeilles-en-Parisis (the place in question) to resent the indignity sought to be inflicted on the reputation of their illustrious fellow-townsmen, by taking the initiative in a movement in favour of a monument commemorative of Daguerre, to which honour he is quite as much entitled as Nicéphore Niepce. The Mayor of Cormeilles-en-Parisis, replying to the application of the Photographic Union of France, requested the members to appoint delegates who should represent the Union at the next meeting of the Municipal Council. In accordance with this request, M. Collard, the president, and M. K. Versnacyen, the secretary of the *Union Photographique de France*, together with M. Glaise, secretary of the *Société des Archives Photographiques, Historiques, et Monumentales*, were so nominated, and after having met to take up their credentials, these gentlemen presented themselves at the last meeting of the municipal council of Cormeilles-en-Parisis. On that occasion they described the course that had been adopted; they maintained the incontestable right of Daguerre to a public monument, and explained how history had been twisted and truth violated by those who had rendered themselves the instruments of a posthumous revenge whose motive and reality is still doubtful. After hearing the delegates, the members of the Municipal Council forthwith unanimously adopted a resolution to start a subscription in aid of a monument to Daguerre, and they themselves headed the list with a donation of 1,000 francs, promising at the same time to defray all the expenses of the fête at which the monument would be inaugurated. The Mayor of Cormeilles-en-Parisis was appointed to join the Council of the Photographic Union as a member of the organising committee, and he was also directed by the Municipal Council to apply to the Prefect of the Seine and Oise for an official contribution from the General Council of the Department. All these proceedings, which have been received by the photographic world with marked satisfaction, prove more than ever that an act of injustice brings with it sooner or later a reparation conferring fresh brilliancy on the reputation which it was sought to prejudice. Had it not been for the objectionable language in which the committee of the Niepce memorial denounced Daguerre as a usurper, in rendering homage to whom France would be committing a continual wrong, Nicéphore Niepce would alone have been honoured with a monument. As it now stands, the two subscriptions will be raised simultaneously, just as the two partners Daguerre and Niepce walked all their life side by side, and there will be nothing but reprobation for the miserable and unjust attempt to blacken the reputation of one of the fathers of photography at the expense of the other—"All is well, that ends well." The expedition of the delegates of the Photographic Union to the birthplace of Daguerre left, as may be supposed, a vivid impression on their minds. Previously to this, they repaired to Petit Bry-sur-Marne, where Daguerre died, an object of general esteem and admiration, and where his memory is still held in high consideration. On the occasion of their first visit to Cormeilles-en-Parisis they were thus able to take with them authentic information derived from an inspection of his venerated tombstone, which the inhabitants of Petit Bry still decorate every year with funeral wreaths; they had also obtained a knowledge of his pursuits while he lived there from the mouth of some of his old friends, who still survive, and had even been permitted to see some of

his works, more especially a splendid picture painted by Daguerre for the church of Petit Bry. At Cormeilles-en-Parisis it was not apparently known, at the time of their first visit, that one of the most celebrated inventors of modern times had first seen the light there, and it was only when they visited the place that the delegates were able to examine, not without natural emotion, the baptismal register which attests the birth of Daguerre. So far back as that a civil register of births was not kept; an ordinary oblong writing-book, whose paper is yellow with age, and whose parchment cover was nibbled by mice and perforated by worms, contains the attestation of the village notary and his witnesses, that his family had been increased by the birth of a male child, whose cries, probably, often invaded the silence of his modest office. The actual house where the rays of the sun first fell on the head of Daguerre, already stamped with the marks of genius, has not yet been discovered, but researches are being made which are sure to reveal the secret. When it is known, Cormeilles-en-Parisis may, perhaps, even before the statue is erected there, become a shrine to which the enthusiasts for photography, daily increasing in number, may direct their pilgrimage. Cormeilles is, moreover, one of the prettiest villages in the neighbourhood of Paris; it lies in one of the most lovely spots in the valley of the Seine, and at the foot of a shady hill, from the summit of which is obtained a magnificent view of the environs of the vast city. In regarding this grand panorama, the eye traverses an atmosphere impregnated with the delicious scents of the trees, and stirred by the fresh breezes of the river with its capricious windings, and penetrates to an endless horizon, where country seats and villas without number indicate the positions of Montmorency, Enghein, Argenteuil, Poitouise, and Maisons-Lafitte. Crowning this hill, which is unfortunately very little known to strangers, are the mills of Sannois and Orgemont, whence the Germans in the last war fired their first shells into Paris. Rather more than half a mile distance from the village of Cormeilles flows the Seine, which at that point waters one of the extremities of the forest of Saint-Germain. The lovely little hamlet situated at this spot is called La Frette, and a short way off the beautiful river joins the Marne, close to the village which for that reason has received the name of Conflans (Confluent). It will be easily understood that a child endowed as Daguerre was would soon, amidst such surroundings, develop a love for the beauties of nature. Is it to be wondered at that he became, while still a young man, an artist painter of some merit, whose landscapes obtained considerable success—that he was the first in France to construct and direct a diorama, of which connoisseurs still speak with enthusiasm, and whose total destruction by fire they remember with regret? Was not a man living as he did among such scenes of natural beauty, where the light displayed so many different tones and rendered so many different effects, more likely than another, by constantly studying that light, to drag from it its secrets—to take it captive in order to compel it to leave the image that it had traced?

A Magistrate's Opinion of the Intelligence of Photographers.—Though Daguerre—I allude to this in order not to make the transition to what I am now going to relate too abrupt—was compelled to make great calls both on his power of work and on his own imagination, to be able to invent that which we now call photography, such great efforts, so much application, are certainly not required to become a photographer. In my last letter that appeared in the PHOTOGRAPHIC NEWS, I said—and I now again repeat—that French photographers, with some few exceptions, take no trouble to raise themselves and their profession to a higher rank of artistic excellence; but I am not, thank God, of the same opinion as the magistrate who, according to the Paris newspapers, will not allow photographers to serve on a jury in the assize courts, the reason alleged being that "photographers are not sufficiently intelligent." The account seems to be perfectly authentic, for it was first pub-

lished in the *Siecle*, which is a trustworthy and important paper, and no contradiction or denial of the truth of the statement has since appeared. It appears, therefore, to be a fact that a magistrate has actually prohibited a commissioner charged with the function of drawing up the jury lists, from including on one of them the name of a well known photographer—one whose profession is given on official documents as "Painter and Photographer"—for the incredible reason which I have just mentioned. The journals justly inquire, what have photographers done to this magistrate that he holds them in so light estimation? Have they produced portraits of him which were rather real than flattering? Have they forgotten to touch out the wrinkles and the warts? Or did the camera omit to shorten his ears? It is difficult to understand why the practice of reproducing on small squares of card the features of our fellowmen, however obscure they may be, should lower our intelligence and pervert our judgment. Photographers have too often been of service to the magistracy that a precedent should be made of the manner in which one has been treated; the Bench has both used and abused them sufficiently to be just towards them. What is most amusing in the whole story is, that the rejected photographer had retired for some time past from the practice of his profession, and so soon as this was made clear to the peculiar, though apparently limited, intellect of the magistrate, he allowed his name to be reinstated on the list from which he had previously caused it to be expunged. Legislation of this kind will probably make a mark, especially in the psychological and physiological world; this second Solomon seems to believe that working photographers have no common sense, but that retired photographers may be endowed with it; so soon as they give up practice they regain their intelligence; they may be capable of reasoning before or after, but never while, they are operators. At the moment when their camera is directed on an object, night suddenly descends upon the spirit: their brain becomes a chamber of darkness, and they do not regain their reason until the sun has accomplished his work. In France, therefore, any one operating on the sunlight must not be allowed to have the same rights as his fellow-citizens. With all due deference to this magistrate, however, and at the risk of having my name erased from the jury lists, I make bold to tell him that, if ever the occasion arises, I should prefer being judged by the nearest photographer to being put on my trial before him.

K. VERSNAEYEN.

AMATEUR PHOTOGRAPHY.

BY CAPTAIN ABNEY, F.R.S.*

As a fact, it can scarcely be gausaid that the art side of nature is capable of giving the most pleasure to the largest number of people. It is not everyone who has the time or talent for studying her from the science point of view; though to those who possess both, the enjoyment felt is perhaps the most intense, and is more frequent, since everything, from the smallest microscopically discerned atom to the loftiest mountain, and to most distant star, is a subject for admiration and research. Nothing is too small and insignificant, and nothing is too large or complicated, for such a student. Unfortunately, there are some who allow both aspects of nature to be unobserved, and these lose a mental enjoyment for which nothing merely physical can compensate.

What is it that makes a denizen of our closely-packed towns wish for a run in the country, and that a pretty part of it? Perhaps it is a longing to enjoy the fragrance of the wayside flowers, to bask in idleness and lazy thought in the shade of the glorious trees, and to listen to the sighing of the wind making soft harmonies in the branches. So far, such longing may be said to be sensuous, but if the mind be touched by the look of nature herself, and the

enjoyment produce mental activity, then the art chord is struck. There are many who feel this enjoyment, and who desire to carry back to their homes some souvenir, however small, of the scene which has given them a sense of mental elevation, and which would enable them to recall the sensations of pleasure they felt stirred within them. The pencil or the colour-box may be strange in their hands, and they may lack the manual dexterity to use them. It may be that they have not time to spare to undergo the drudgery of learning the mysteries of such art, and shrink from the ordeal of wading through those freehand copies of curious scrolls which delight the great ones at South Kensington, and without which the eye and hand are not supposed to be trained. Can nothing be done to help these—no other means of cultivating the art innate within them? Fortunately there is—photography. A few years back photography was a black art, judging by the hands and often the clothes of its devotees, and this alone prevented its employment by many who otherwise would thankfully have made it an ally. But *nous avons change tout cela*. Progress has been made in the manipulations, and processes have been so simplified that the stigma of "uncleanness" has been taken away, and a persevering tyro may command success. The influence that photography has had on art is undoubted, and without offence to our prominent artists, it must be said that it has made the pictures of to-day truer to nature than those of fifty years back.

A day in the country to one accustomed to the camera means something totally different from a day in the country to one who has no pretence of a love of art, and it behoves the former to beware of seeking the companionship of the latter unless an explicit compact be made beforehand. The mere pedestrian whose sole object is to exercise his limbs, and cover so much ground during the day will, as a rule, consider the devotee of photography a nuisance, and his camera an unmitigated bore. The companionship of a brother in the art, however, is to be sought, as there is a certain healthful stimulus given to the perceptions through competition. We have been frequently asked as to the apparatus required by the amateur for his day's excursions, and it may probably be an encouragement to some if a few words are said on the subject. The sizes of plates that are used vary so much that a selection is somewhat difficult. Of one thing we are certain, that in order to prevent the day's outing from being anything but a pleasure, the load carried should be light. Some of our mountaineers tell us that from fourteen to twenty pounds in weight may be carried conveniently on one's back for a whole day without much sense of fatigue; but it must be remembered that this has reference to those who are in tolerable training. For an ordinary mortal the weight carried should not exceed fourteen pounds, and even then the load should be distributed about the body in such a manner that fatigue of any one part is avoided. A friend of ours, who is a great pedestrian, and every summer wanders into the Tyrol or Switzerland, and carries his knapsack for his whole kit, manages to include about four pounds weight of photographic apparatus with him. His plates are small, about three inches square; and he is able to take his camera, and perhaps three dozen dry plates, with him, and thus to secure reminiscences of his travels—and very charming they are even to those who have not had the fortune to have made a personal acquaintance with the scenes themselves—beginning, perhaps, in some quaint Swiss town, gradually taking you up the icy slopes of Monte Rosa, and finally landing you at Boulogne. Such a size of picture, however, is usually too small, and our friend finds the interest in them increased many-fold by enlarging them on his return home. For the ordinary amateur this last process is not to be thought of unless he have spare time at his command, or can afford to get the enlargements made for him by some professional; so we recommend a larger size of picture, say 7¼ inches by 5½ inches. This gives a pretty shape, not too narrow, when

* *Cassell's Magazine*.

the pictures have to be taken with the $7\frac{1}{4}$ inches in a vertical direction, and yet not too broad for the picture when the greatest length is horizontal. The equipment, with its weight, is shown in the following column:—

Camera	lbs.	3
Dark slide		1
Changing box to hold one dozen plates ...		5
Lens		$\frac{1}{4}$
Focussing cloth		$\frac{1}{4}$
Set of camera legs and stand		2
		11 $\frac{1}{2}$

Here, then, we have an equipment weighing nearly twelve pounds, with which we may be able to secure a dozen pictures, and which can be slung about the body in such a manner as to distribute the weight. The changing box is a box holding a dozen plates, which can be prepared by a method we shall give presently, and from which a plate can be placed in the dark slide without seeing light. The exposed plate is first slipped into the box, and the dark slide is then refilled from the changing box itself.

Such a kit is very different from that required in the old days, when the wet process was the only one which would give certain results; for then we were troubled with dark tents, bottles of solutions, and any number of et ceteras, in order that the picture might be developed on the spot. By the present arrangement we are saved all these encumbrances, and the photographer may plant his camera on any spot to which he can travel himself, without being hindered by the consideration as to whether his other baggage can follow him. As to the preparations which a day's outing require, they are small, particularly if economy is not the great object; for in the market there are numerous brands of dry plates, more or less good, which can be made use of at a moderate price. Our own advice is to purchase one kind of plates, and prepare the others. The plates to be purchased are those known as gelatine plates, and they are most excellent for certain purposes, such as instantaneous pictures of cattle, street scenes, and such other views in which there is a state of unrest in parts. They are exquisitely sensitive, and an exposure in the camera of a quarter of a second in bright light will give every detail which is thrown on the focussing screen of the camera. For ordinary views, however, we recommend the amateur to purchase from some well-known house a few ounces of what is known as washed collodion emulsion, and to prepare his own plates, and if to such an emulsion we recommend the addition of one-sixth part of its bulk of a solution of gum guaiacum in alcohol, we think the chances of success are increased. Then the manipulations in the preparation of the plates are so simple. The problem is reduced to this: in a room lighted by a candle shaded with a red shade you are given a bottle of sensitive emulsion and a clean glass plate; it is required to coat the latter with an even film of the former. That is all! There is really no difficulty in it. The emulsion flows over the plate like oil, and any excess is allowed to drain off. When the solvents employed in the emulsion have partially evaporated, the plate is reared up in a box to dry. This desiccation takes, perhaps, one hour to effect; when complete it is ready to be transferred to the changing box already described. The dozen plates, in fact, may be prepared at nine o'clock at night and be ready for use at ten, if the room be moderately warm. Only beware of dust, and the plates will be a success.

(To be continued.)

PHOTOGRAPHY AS APPLIED TO THE REPRODUCTION OF PLANS AND DRAWINGS.

BY DAVID TOWNSEND, B.S.*

URANIUM.—The salts of uranium are affected similarly to those of iron, but they offer no advantages over the iron

* Continued from page 417.

salts, and are besides very expensive. Those who desire to try them may use the following formulas.

A good quality of paper must be taken and sensitized by floating for six or eight minutes on a solution of

Uranic nitrate	1 part
Dist. water	60 parts

When dry the paper is exposed under a drawing for ten or fifteen minutes, and is then removed and developed by floating on

Ferricyanide of potassium... ..	1 part
Water	250 parts
Nitric acid	2 drops

In about five minutes a brown picture will appear, which is fixed by washing in slightly acidulated water.

To produce a grey picture the print is floated on a bath of

Silver nitrate	1 part
Water	20 parts
Acetic acid	a trace

The development is very rapid in this solution, being complete in thirty seconds, after which it must be taken out and thoroughly washed in clean water. Red, green, or violet pictures may also be produced, by developing on ferrocyanide of potassium, perchloride of iron, or chloride of gold.

CHROMIUM.—The fourth and last salts are those of chromium, only two of which are commonly used, namely, the bichromates of potassium and ammonium. These form the basis for a number of valuable processes, one of which is at present attracting much attention in Germany, where it has been carried to a high state of perfection in the reproduction of drawings and fine engravings. It is called the

ANILINE PROCESS.—This was invented by Mr. Willis in 1864. It depends on the fact that when potassium bichromate, in the presence of organic matter, is exposed to the action of light, free chromic acid is formed, and the protected parts, which still remain as bichromate, form aniline colours when exposed to the vapors of aniline salts. The process, in detail, consists of the following operations:—

(1) Sensitizing the paper; (2) Exposing; (3) Fuming; (4) Washing.

(1) *Sensitizing.*—The best Saxe paper must be used, as no other will give satisfactory results. The sensitizing solution consists of

Potassium bichromate	1 part
Phosphoric acid, sp. gr. 1.124	8 to 10 parts
Distilled water	10 to 12 "

The paper, after being cut and the finest side selected for use, is pinned to a clean, flat board. Some of the solution is poured into a dish, and the paper is sensitized by means of a stiff brush about one inch wide, which is dipped into the liquid and then painted on paper, first lengthwise and afterwards across, without renewing the liquid on the brush. Finally, a soft camel's-hair brush, about three inches wide, is used to remove all superfluous liquid and smooth out any streaks left by the first brushing. The solution may also be applied with a soft sponge, but the first method is preferable, as the fingers are not then brought into contact with the bichromate, which is a violent poison. The sheet is now hung up and allowed to dry slowly, it being complete in from fifteen to twenty minutes. The operation should be performed in a dark room lighted with a lamp having a yellow chimney. Ordinary yellow light is not sufficiently non-actinic, owing to the extreme sensitiveness of the paper, which is easily affected by the least light. When dry, it may be preserved for some time unaltered in the dark. The brushes should be thoroughly washed each time they are used, and carefully protected from dirt.

(2) *Exposing.*—The prepared paper is now placed in the printing frame, under the tracing, covered with a black cloth, and carried into the sunlight. The length of exposure will vary with the time of the year; in summer being about twenty seconds, and in winter forty seconds. The surest method is to use Vogel's photometer, and carry the

exposure to sixteen degrees, but as this cannot always be obtained, experiments may be made to determine it. This is the most important part of the whole process, because undue exposure will not reduce the bichromate sufficiently, and over-exposure renders the paper less liable to form aniline colours. When the paper is rightly prepared, it should be a light yellow colour, and after exposure, on opening the frame, a faint yellow picture will be observed on a greenish ground.

(3) *Fuming*.—When the exposure is judged sufficient, the cloth is replaced and the frame carried back into the dark-room, where it is opened, the picture removed, and pinned to the lid of a fuming box. The box is provided with a sheet of glass, on which is blotting-paper soaked with a solution of

Aniline oil 1 part
Benzinc 10 parts

and which can be lowered or raised at pleasure by means of cross-pieces of wood at different heights. It is allowed to remain thirty minutes, when the picture, if rightly exposed, will be sufficiently developed, and will show a dark brown or purple picture on a grey ground. If the image is rather faint, it should be fumed longer.

(4) *Washing*.—On taking out the print, it must be washed for some time in at least four changes of water,

when the colours will be fast, and, after drying, the picture is finished. Great care must be taken not to handle the sensitive paper any more than is absolutely necessary, and then only with perfectly clean hands; also to perform all the operations in absolutely non-actinic light.

In review, we conclude that, in point of cheapness, the blue process has the preference; but, for certainty of results and general reliability under all conditions, the silver process is the best. I should, therefore, recommend it in all cases where first cost will not be a consideration compared to convenience and saving of time.

ENLARGING CAMERA.

BY FRED. T. WEBB.*

For producing a large print from small negative or a large negative from a small transparency. Many amateurs (myself included) often obtain a negative yielding proofs that are (to them) all that could be desired, and wish they could produce them on a larger scale, but owing to the expensive apparatus which they would have to purchase they are (though often reluctantly) obliged to abandon the idea. Therefore I describe a camera which anyone may make, and from the sketch which I enclose, with explanations, have no doubt but some of your readers will appreciate it.

A, mirror to reflect light through negative or transparency B; C, lens; D, black calico lined with yellow, with wire rings inside, and india-rubber bands outside to form the bellows; E, space for dark slide when taking the picture; F, sliding shutter; G, frame screwed on to boards H; I, piece of cork to press against the glass plate; K, peg to adjust the focus. The dark slide can be used as a substitute for focussing frame by placing a piece of ground glass at J, which can be removed to make room for glass which supports paper or intended negative. The frame G, 46in. by 14in., the holes for the pegs K to be 1in. apart, the dark slide to take glass plate 16½in. by 12½in., for pictures 16in. by 12in., the frame L to be 1½in. thick. When enlarging a ¼ plate negative four times, after allowing ¼in. margin all round, in small negative to 16in. by 12in., the distance from negative B to lens C will be 7½in. (with a lens of 6in. focus); and 30in. from C to E, which can readily be measured off by the pegs K. To enlarge three times will be 8in. B to C, 24in. C to E, thus enlarging to 9in. by 12in. To enlarge twice the size will be 9in. from B to C, 18in. from C to E. To copy the same size B to C 12in., C to E 12in. When copying C.D.V. the calico bellows from B to C and mirror A can be dispensed with.

SOLAR ENLARGEMENTS.

At a recent meeting of the Chicago Photographic Society, Mr. Fitzgerald called attention to the solar enlargements exhibited before the Society, made by the Wolfe and Stigleman processes, a mode of producing enlargements by

the solar camera said to give very fine results. He "though he had done as fine work in his way, which, for the benefit of the members and others, he would briefly state. If a new negative is to be made, have some glass, one side of which is ground very free; make your negative then for the solar in the usual way, flow it with a water varnish, easily made, as I will explain further on. After the negative is dry, retouch it in the usual way, and then varnish the ground side with any alcoholic varnish (Mountfort's is excellent); heat the negative slightly. As usual when varnishing, this makes it translucent, and the enlargement will be as fine, if your negative is good, as any contact print. You can also use the same negative for the usual contact prints by printing under ground-glass or tissue-paper. If you want to enlarge from a negative from your collection, take off the varnish by laying it in a dish of alcohol, then reduce the intensity by any of the usual methods. I use mercury and cyanide, varnish with the water varnish, and laying the negative on a clean blotting-pad, face down, take flour of emery and water, with a small piece of glass, and, rubbing briskly, grind the smooth surface fine and even; wash carefully, and dry; retouch, varnish the ground side as before, and use in your solar; the negative can be used for contact prints also. To make the water varnish, which, by the way, is the best retouching varnish made, as follows:—Take

Orange shellac 5 ounces
Borax 1 ounce
Water 1 pint

Digest at nearly the boiling point until dissolved, then filter.

IN MEMORIAM.—OLIVER SARONY.

It is our painful duty to announce the death of Mr. Sarony, of Scarborough, one of the most successful and distinguished of photographic portraitists. His history and career have been a living monument of the results to be obtained by energy and enterprise. Oliver Francois Xavier Sarony was in his sixtieth year, having been born in February, 1820. He was of Italian origin, his father having been an officer in the Austrian army, retired from which he settled in Canada, Oliver having been born in Quebec. The elder Sarony dying, Oliver and his brother Napoleon were thrown on their own resources at any early age, and we find Oliver a youth in his teens, nothing daunted, establishing a business in travelling from Canada with beaver furs for hats into New York, and carrying also contraband silk for silk hats. He was soon to abandon, however, this at the time fairly lucrative trade.

Whilst in New York one day he was taken by his brother Napoleon—who, like more than a child, had established himself to make a living in that city by lithography—to see a most wonderful sight, a machine which took portraits. Oliver's wonder and admiration took a practical form. He at once asked the Daguerreotypist for what sum he would teach the art and supply the apparatus. Ultimately we find that by piling together all his means, and adding thereto his silver watch, young Oliver had become possessed of a camera, lens, and complete Daguerreotype equipment, together with the knowledge and skill to use them. This was soon after 1840. He practised his newly acquired art with varying success, but on the whole with satisfaction, in Canada and the States. Early in his career he was urged by a captain of a vessel, whose portrait he had taken, to visit the old country, where, with such an art, he might make a fortune. He sailed with the captain for an Irish port, and proceeded to practise his art in Ireland as early as 1843. Shortly afterwards he reached England, and commenced a line of business for which he became famous. He fitted up a very handsome and commodious travelling studio, and either personally or by an agent showing specimens to the gentry resident in the district he passed through. As he at all times produced the very highest class of work, he found plenty of patronage. He also occasionally travelled from town to town establishing studios, which, after working successfully for a few months or more, he would often sell, and settle for a time elsewhere. Eventually he settled in Scarborough in 1857, and established branches in other important large towns. To a rare amount of business tact and shrewd enterprise

Mr. Sarony added a fine artistic taste and manipulative skill, and his work, and all sent from his establishment, was of the highest quality, and generally in the newest and best styles which had been introduced into the art. He was also ingenious and practical, as many of his mechanical inventions attest.

He was one of the earliest to appreciate the value of Swan's carbon process, and to adopt it regularly in his business as a portraitist. When the next great advance in simplicity of working pigment printing was made by Mr. Johnson, Mr. Sarony was quick to see and adopt its advantages. He was always in the van of practical photography, accepting every improvement with eagerness, and introducing not a few. His name was, to some extent, at times associated with process vending, a form of business which can rarely be carried out without gaining obloquy, as the purchaser of a process which he fails to work satisfactorily rarely blames his own want of skill. We can say without hesitation of Mr. Sarony in this regard that he never sold a process which had not excited his enthusiasm with the beauty of the results it yielded in his hands, and which in his view was not quite new. He was at all times full of keen restless enterprise, which found its vent in some very great works, by which his adopted home, Scarborough, greatly benefitted. The handsome series of buildings, now in a fashionable neighbourhood named Sarony Square, was, when he first began to build upon it, a barren piece of land in an outlying district, and the improvement in South Cliff has done much to establish Scarborough as the Queen of fashionable watering places. The studio, in the centre of the square, which has been described in those pages before, is most magnificent in its appointments. His most recent enterprise in connection with Scarborough was the erection of a beautiful circus, considered the finest in England, capable of accommodating 2,500 persons.

Returning to his photographic enterprise, Mr. Sarony's especial delight and pride was to take an order for an oil-painted enlargement from a customer whose original purpose was to have a dozen card portraits. We have seen him engaged in such an enterprise, and watched his almost child-like delight in the success of his efforts. Selecting the most pleasing of two or three negatives which had been taken, it was handed into a distinct department fitted up for rapidly producing transparencies. A transparency obtained, it was placed in a magic lantern kept ready, and a life-size image was thrown on the screen. Mr. Sarony had, in the meantime, invited the sitter and his wife into a gallery of life-size portraits well painted in oil, and handsomely framed. These, of course, elicited admiration, and eventually Mr. Sarony led his visitors into the room where a fine portrait of the gentleman was presented life-size on the screen. The effect, as all photographers know, is very striking and effective, and fully admits of a little eloquent talk on its fitness for painting. Mr. Sarony talked well and gracefully, with a frank candour that won belief; and on the occasion in question he took an order for an "oil" at sixty guineas.

Mr. Sarony was a man of considerable ability in other directions besides photography. He was possessed of very great physical strength and activity, and was a fine swimmer, fortunately for several who owed to him their rescue from drowning during the course of his life. His memorable attempt to save life in a storm off the Scarborough coast in 1861 is re-told on another page, and forms a tale as thrilling as the wildest romance. For this he received the gold medal of the Royal Humane Society, of which he was very proud, his kindly and generous nature rejoicing more in this tribute to his bravery and unselfish risk of his own life than in the success of his commercial enterprises. His most intimate friends knew him as a generous, large-hearted, and good-natured man; whilst the majority of our readers knew him as a skilful photographer of rare enterprise and great success.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

PHOTOGRAPHIC PRIZES.

The following are the prizes awarded to professional and amateur photographers exhibiting in the Photographic Department of the Royal Cornwall Polytechnic Society. A full report in our next:—

Landscape.—No. 593. English and Irish scenery, Payne Jennings, 1st silver; 625. Oxford and Cambridge Boat Race (instantaneous), Wratten and Wainwright—1st silver; 594 to 600. Willis's Platinotype Process—2nd silver; 616. Interiors, R. C. Lenthall—2nd bronze.

Portraiture.—No. 590. Portrait Study, W. Gillard—1st bronze; 588. Portraits by the Gelatine Process, Hills and Saunders—1st bronze; 589. Three Portraits, E. Greaves—1st bronze; 576. Group (dry plate), Russell and Sons—2nd bronze; 626. Enlarged Group, G. Cocking—2nd bronze.

Amateur.—Nos. 702 and 703. Arctic Photographs, J. A. Grant—2nd silver.

Liverpool Dry Plates.—711. Three Frames of Views (dry plates), Andrew Pringle—2nd silver; 717. Transparencies, H. Manfield—1st bronze.

Photo-Appliances Department.—No. 741. Changing Box, G. Hare—1st bronze; 745. Duplex Lantern, H. Kevil—1st bronze; 747. The Malden Triple Lantern, J. Middleton—2nd silver.

“LOOKING BACK.”

BY AN OPERATOR.

INTRODUCTION.

GENTLE READER! I have no doubt but that my simple title has called up in your mind's eye a host of varied scenes—scenes both sad and gay! For who can look back for a few years without mentally marking some gloomy epoch, some heavy shadowed Rembrandt picture, of our private life, when grim death has marshalled from our sphere some loved and cherished one—when the cheery voice was silent, when the kindly heart had ceased to beat—when the cheerful home was sad, and its homeliness covered with the trappings and suits of woe? Yet, side by side with this (so wonderfully are our lives blended by sunlight and shadow), will start up the recollection of some happy day, a bright oasis easting forth its grateful perfumes on a barren field, and softening with its light the darker picture of the past.

Such were my feelings when the above title to these sketches was suggested. The instantaneous thoughts called up were anything but pleasant, and in fact I eyed it askance and with something of aversion. Presently, as I gazed into the firelight, the gloomier pictures rolled away, and sunny spots appeared; brighter and brighter they grew; one by one my old hopes were revived; my youth renewed; from their far-spread graves my friends once more were with me. I moved in the past—in the spring-time of my life—in the season of flowers and green leaves and whispering winds, when the heart was light and the brow unclouded with care!

Some of these bright spots and shifting scenes I mean to place before the reader, my aim being more to give half an hour's amusement rather than impart knowledge, although possibly I may be afflicted by the same disease as a well-known writer, so that particles of wisdom may ooze out of my pen along with the ink, without my being aware of it.

I finish this short introduction with the words of Othello, promising to

—“Neither extenuate,
Nor set down aught in malice.”

CHAPTER I.

MY FIRST SITUATION—THE “FIRST PHOTOGRAPHER”—A NEW DEVELOPER.

YEARS and years ago, when ladies wore eriuolines, and gentlemen peg-tops—when the Daguerreotype and glass

picture had got their parting kick, and King Silver-print ruled instead—when full-length pictures were the fashion, and the photographer had to dispose, gracefully, of the legs and arms of the gentlemen, and the cart-loads of steel hooping and drapery of the ladies—*condensing*—condensing them into the smallest room possible, so as to show off the pedestal—the fluted column of the open easement that looked forth upon the proverbial eternal summer with the ravishing landscape!—I assure you it took a good deal of material to make up a proper *carte-de-visite* in those days! Here let my brother-workmen pause for a moment, and, looking back (if they can) the matter of twenty years, view the difference between the tiny, miserable, cross-legged, arms-akinibo picture of the past, and finely-lighted, beautifully-posed, and highly-retouched cabinet heads of the present.

Comparisons are odious! Odious enough in this case, for, truth to tell, I feel rather hysterical when I happen to come across any of my very young work. To an old hand like myself there is an awe and sublimity about those serewed and stuck-up figures that rob one of the hearty laugh that the younger learner generally indulges in when he happens to stumble upon them. To me they seem hallowed shades of a generation that has passed away—remnants of a crude barbaric and remote period!

Yes; those were the days when retouching was unheard of, when the negative had to be made dense to hide the wrinkles and freckles, and had to be re-developed by main strength, so to speak—those were the days when I had no caes or razors!

I used to delight in journeys then, and I can recollect how proud and big and manly I felt when I first set foot in a certain northern city. I was out in the world, and was about to earn my own bread. I had thrown off the leading strings of my parents, and gone forth, *sword in hand*, to open the oyster myself. Everyone must recollect the perfect sense of freedom that stole over them when they found themselves without the range of their guardian's watchful eye—when, like me, they went out full of high hopes to fill their first situation.

I was engaged to a Mr. Ballarat as assistant. Ballarat was a strange, wild, but withal honest fellow. He had seen a lot of the world, and had mingled with a class that did not tend to refine or heighten his aspirations. He had been in Australia at the diggin's, and, as he said himself, “he lost a lot of good time and a few good principles there.”

Having a natural tendency to chemical science, luck at a little bit of research threw him in the way of the Daguerreotype; “and my boy,” he exclaimed with a wave of his hand, “I was the first to produce those pictures in Melbourne!”

He was the first—the very first that I heard exclaim those words—those wonderful words that I have heard repeated in solemn, truth-inspiring tones, hundreds of times, the vicinity being the only alteration.

He was quite a character—that first photographer! Go wherever you like, you are sure to meet him. It is a hundred to one he has left the profession and ekes out a shabby-genteel existence in canvassing for portrait clubs, life insurance societies, or the new Encyclopedia. He is a wonderfully shrewd fellow, and by instinct knows a photographer a street off. He will watch his chance for weeks, and will pounce upon his victim when least expected. He then goes to work in a roundabout way, and at length surprises his victim by a few technical questions, as “Do you use the phosphate toning now?” or “What re-developer do you have?” This naturally surprises the victim into exclaiming, “Why, you seem to know something about photography!” “I should rather think so,” is the answer given with a knowing wink. “My dear sir, I was the first man that ever used a camera in this town!” Should the victim be green to his class, and express by word or look any kind of interest, he is imme-

diately button-holed, and has to listen to a disual romance, finishing up with the remark, "You know, you seem a good sort of chap, and if you like to come up home, I'll let you see my old apparatus, fuming box, and everything complete!" He strikes an attitude here, and looks to his victim for profuse thanks.

My readers are sure to know the first man: there certainly must be first men; but when you meet as many as twenty-five claimants in one small place, your reason tells you that twenty-four of them are mistaken.

When I was in Iceland a Dane joined our bivouac at the foot of Mount Heela, and Tom Howie, of whom I shall tell you more anon, managed to talk to him by means of signs and clippings off all the languages, dead or quick. When I asked Tom what he said, he replied: "He says he was the first man that took a photograph in Copenhagen."

Still, I have little doubt but what Ballarat took the first pictures in Melbourne. It seemed to please him to say so, and it did no one any harm. At the time I engaged to him, he had a steady-going middle-class trade, employing four young ladies—two of whom did the printing—a boy to clean plates, &c., and your humble servant. If Ballarat was not the best photographer, he was the biggest I ever met with. He stood over six feet, and stout in proportion, with a great, good-humoured face adorned with hirsute appendages in the shape of huge bushy whiskers. He had a lounging gait, and altogether smacked of the bush.

To his strict attention to cleanliness he to a great extent owed his success. "Dirt is the root of all evil, my boy," he used to say—a fact that stands undoubted to this day. If there was the slightest spot on a print, it was torn immediately; the least blur on a negative, it was condemned. I know this to be the rule in every high-class establishment, but neglect of the said rule was the rock on which so many of the early photographers got wrecked.

"Come, I will show you over the shop," were his first words after a hearty shake of the hand. "First let us go to the glass room." We accordingly went there, and found it to be small, with a low ridge roof, such as almost all the studios were in those days. When Ballarat was operating upon a family, it was crowded. When he walked from the camera to adjust something about the sitter, it shook and trembled under his tread; and when he laughed to reassure his sitter, the glass overhead jingled unpleasantly. Still, good pictures were obtained there with little trouble at any hour, for, either by luck or good management, Ballarat had built his studio to a pure north-east light.

"Small, my boy, but compact," was Ballarat's comment as he glanced complacently round the room. "Now for the dark room. Recollect, my boy," he continued, as he paused in the doorway, "that all that transpires within the sacred precincts of this hallowed spot is secret—secret and silent as the grave! When once within the mystic light of the yellow window, you can drop the complacent smile that deludes your sitters, and pull faces at them—yea, shake your fist at them if so inclined. Here you can, with impunity, give way to profane language when unruly infants try your temper too much. Here, in short, you may riot in exclamations unfit to be published in the weekly journals; but have a care to go forth to the actinic light and your sitter with an air of success, and a beaming countenance. That's the way I do it, my boy, and it answers splendidly!"

Here he winked and chuckled so heartily that it was impossible not to join him. After being duly shown the bath, developer, cyanide, &c., he suddenly turned to a shelf, under which sat the dark slides, and, pointing with his finger, said, with a theatrical air, "Behold!"

Where he pointed stood a bottle that would hold about a quart—it was then about three-fourths full—and on it

it was a large label, indicating it to be "The New Developer."

"Ah, have you a new formula, then?" I asked.

He did not answer me in words; but while he grinned knowingly, he reached the bottle from the shelf, and, uncorking it, held it close to my nose. "Smell," quote he laconically.

"Precious lot of alcohol, anyhow!"

He burst into a loud laugh at my remark, and bringing forth a wine glass filled it with the "new developer," and handed it to me, with the single word, "Taste."

I did taste, and found that the "new developer" was nothing more nor less than good old Irish whiskey.

"Never make a mistake between the two," he exclaimed, after smacking his lips over the empty glass. "Not that the plates would be any the worse of the *new*, but my stomach might be from an application of the *old*."

Such was my first employer. I stayed with him over two years, and never was happier in my life. "Come, my boy," he would say on a gloomy winter evening, "bring forth the music, and let us be gay. If there were no sunshine, there would be no shadow—and it is the shadow that makes the picture."

We were very much attached to each other, and were very unwilling to part. You shall learn in my next what induced me to leave him.

(To be continued.)

MR. O. SARONY.

THE following notice of the deceased appeared in the *Scarborough Daily Post* of Saturday, August 30th.

"In our issue to-day we announce the death of Mr. Oliver Sarony, of South Cliff, Scarborough, which melancholy event occurred at his residence early this (Saturday) morning. About a month ago the deceased gentleman had a paralytic stroke from which he never fully recovered. He was attended by his medical adviser, Dr. Wright, but the efforts of the latter failed to check the ravages of the disease, which resulted, as already stated, in his death at five o'clock this morning, when deceased passed away very peacefully.

"Mr. Sarony, who was fifty-nine years of age, was a man of active business habits, and was well-known, both in Scarborough and elsewhere, for the enterprise he displayed in connection with the profession with which he has so long been identified, and which he has conducted so successfully. He first came to Scarborough about twenty-two years ago, and originally resided and carried on business in a house in South Street, South Cliff. His fame as a photographer rapidly spread, and the business increased very considerably. At that time what is now known as Sarony Square was barren land. It was purchased by Mr. Sarony, who erected the spacious and elegant studio at present existing there. From this magnificent establishment, which may be described as one of the most unique and complete to be met with in this country, a most extensive wholesale and retail business has been carried on in every department of art, until the name of Sarony has become a household word in every town in the kingdom. Not only has deceased been extensively patronised by the nobility and aristocracy, but he has received various marks of Royal favour, he having received the commands of Her Majesty the Queen, their Royal Highnesses the Prince and Princess of Wales, and other members of the Royal family to paint portraits, &c. It is not too much to say that Mr. Sarony well merited the high honour thus conferred upon him, for his productions have long been pre-eminently as works of art.

"During the time that he has been in Scarborough Mr. Sarony has been a conspicuous citizen. Starting in life in a humble way of business, he reached the very highest position in his profession, and the energy and enterprise thus displayed entitled him to the respect of his fellow-townsmen. Deceased was of a kindly and generous disposition, and was ever ready to assist any project that had for its object the amelioration of the condition of his less fortunate brethren. That he was not wanting in those qualities of courage and manly vigour which are ever and anon called into play in order to meet some sudden emergency he proved in a significant manner some years ago

on the occasion of the wreck of the *Coupland*, which vessel was driven ashore in a heavy storm opposite the Spa, an event rendered memorable by the lamentable death of Lord Beauclerk and others. It was on the 2nd of November, 1861, that the schooner *Coupland*, laden with blocks of granite, from Aberdeen, attempted to enter the harbour here during a terrific storm and heavy sea. Being taken aback on rounding the pier, her sails were disabled, and the vessel drifted and ultimately struck on the sands directly opposite the orchestra at the Spa, and perhaps not more than twenty yards from the sea-wall. It was on a Saturday afternoon, about four o'clock, and a number of people were on the Spa promenade watching the ill-fated vessel, amongst whom were Lord Londesborough, Lord Beauclerk, Mr. Sarony, and others. The billows washed against the sea-wall of the Spa with such terrific violence that the massive stones of the parapet were dislodged for the entire length of the promenade. The lifeboat was manned and launched, but could not live in the dreadful sea. It was dashed with relentless force against the wall and upset, her gallant crew being left in the angry waters struggling for their lives. A scene of terrible excitement ensued. Those gentlemen on the Spa rushed down the incline to render assistance, and one boatman named James Banks was rescued by Lord Londesborough. It was in this crisis that a heavy wave struck the gallant band, and threw many of them into the sea. Several of them were dashed against the sea-wall, and some were killed. Lord Beauclerk was amongst its number, though he was not killed on the spot. He was washed to the foot of the incline, when Mr. Sarony, seeing his Lordship's peril, bravely ran down the incline, and single-handed, succeeded in tying a rope round the body of Lord Beauclerk. The latter was drawn up the incline, but he shortly afterwards expired. Meanwhile Mr. Sarony had a terrific struggle for his own life. After securing the rope round Lord Beauclerk (but without a rope round his own body), he was carried out to sea many times and dashed about like a toy on the crest of the surging billows. In this awful crisis his great presence of mind and experience stood him in good stead, for instead of battling with the waves he rolled himself together and let them bring him back, when he was seized by Mr. John Bell and others and dragged up the cliff by ropes. Mr. Sarony, however, was so terribly exhausted that three hours elapsed before circulation was restored. So nearly had he sacrificed his own life in attempting to save others. In addition to Lord Beauclerk, Mr. Wm. Tindall, son of the late John Tindall, Esq., and several other individuals, also lost their lives. The crew of the schooner were ultimately got off with the rocket apparatus in a dreadfully exhausted state. Deceased was often and justly complimented in after life for the praiseworthy way in which he distinguished himself on that memorable occasion. We understand that the business of the firm will be carried on as usual. The deceased leaves a widow, but no children.

SOME CURIOUS EXPERIMENTS.

At a recent meeting of the Chicago Photographic Association Mr. Joshua Smith read the following paper:

"During the year 1876, while pursuing some experiments on the development of the latent image, I noted some very interesting and useful results, which to-night I will place before you as the sequel to the demonstration I made before the Association during the autumn of that year. I was using bromide of copper for intensifying, and it occurred to me that the negative might be converted into a positive with nitric acid, but on trial the acid produced no effect. I then prepared another plate with the bromide of copper, and placed it in a dish containing hyposulphite of soda, when the image entirely disappeared, leaving nothing but the clear glass. I now began to experiment to recover the lost image, and after washing the plate, flowed upon it a solution of pyrogallic acid and silver. The image immediately appeared, and was brought to a full printing strength without trouble, having all the detail it possessed originally. This same plate was again treated with the bromide of copper solution, the image dissolved again with the hyposulphite of soda, and again developed, and I continued the same treatment for at least six times, and without in the

least endangering the film; the only precaution necessary being the careful washing of the plate to avoid stains. The pyrogallic acid solution used was twenty grains strong, with about two drops of silver solution to the ounce. This method offers something for those who are in search of a way of producing 'spirit' pictures. It is also very useful for reducing the negative for solar work, as the strength of any negative can be reduced to any point required. It is also a very pretty and useful experiment in the lecture-room, as the demonstration can be made in a glass bath, and in either gas or daylight. I have tried various other methods, but this in my hands gives the best results."

Correspondence.

MOUNTING MATERIAL.

SIR,—As I so many times have read about new mounting materials in the PHOTOGRAPHIC NEWS, I suppose many have yet the same trouble with them as I had, until it turned up in my memory the paste I used when, as a school-boy (happy days, alas! they were a long time since), I made my paper kites and balloons.

Bring 100 c.c. of water to the boiling point, and take 20 grains of wheaten starch, and make with about 15 c.c. of cold water into a thick paste. As soon as the water is boiling take it and pour in in *one swoop, not slowly by-and-bye*, into this paste, and immediately begin properly to mix it up. The result is at once the finest mounting material, which, after the addition of sufficient of carbolic or salicylic acid, and kept in a cool place, will only deteriorate by drying up. I wish to call this the receipt out of the workshop (or, less jarring for minds of a more æsthetical or poetical term, studio or atelier) of "Old Great Grandfather," and am certain the whole globe will agree with me it is the best.

In pouring a thin, cold paste into boiling water, or boiling a thin, cold paste, as is generally recommended, a sufficient homogeneity is not attained, which is very natural, as the destruction of the original form of the molecules is not rapid enough; too much energy is lost in the re-arrangement of the new compound. In Old Great Grandfather's receipt, the destruction of the original form of the molecules is so rapid, and the energy destroyed so long, that a serviceable compound necessarily is the result.—I have the honour to be, sir, yours, A. C. S.

PHOTOGRAPHIC COMPANIES.

DEAR SIR,—Are our friends the photographers becoming more credulous, or softer, than hitherto, that they are to be surfeited with companies? In your last issue I noticed a "New British Industry" (worked by Germans!) Is it not somewhat hard, seeing the large number of British workmen unemployed, that we are asked to support foreigners? It is called the British Mount Manufacturing Company. The prospectus states that the photographers of the United Kingdom number 6,000! A third of that number, or say 2,100, is the maximum I could ever find or hear of, and the average consumption of mounts cannot be more than 10,000 or 15,000 per annum at the outside. I know one or two photographers using very large quantities, but to use nearly a 1,000 mounts daily he must be a "rara avis" indeed, and with one (I suppose a dealer) using 2,000,000 per annum the resources of the "Company" must be severely taxed to supply them. The capital, too, is fabulous for such a concern. I know one firm doing as large a trade as the "Company" with one-fifth of the capital or less. A lad can turn out over 5,000 mounts daily, and a man 8,000 to 10,000. So that four printing presses with two men and two boys would print about 140,000 mounts per week; a lad can round-corner 10,000 mounts in a day (no need to call in foreigners for this branch of the business). As to the "Mangle" employed to polish the cards after printing, one

old gentleman at twelve shillings a week can generate all the steam power necessary for any number of mounts. I do not object to companies with a sufficient "*raison d'être*," but I do object to those with little or none at all. From my experience of the photographic trade I believe they will require a more plausible "*raison d'être*" than the one advanced. I enclose card, and remain,—Yours obediently,
MAGNUS VERITAS.

GELATINE PLATES HONEYCOMBING.

DEAR SIR,—I have been trying my hand at gelatine emulsion making according to Mr. Jarman's method as published a short time back in the NEWS. All went on smoothly enough until I came to the coating of the plates (except a little difficulty in getting the emulsion to set previous to washing), when, instead of the ever matt surface that the Swan plates have, my plates have quite a honeycomb appearance when dry, though they appear right enough when just coated, but on setting, soon begin to present the above appearance.

Thinking the first time I had made some error in emulsifying, I commenced a second time at the beginning, but still the same result. If you can point out the probable cause of my difficulty, I shall feel greatly obliged.—Yours truly,
B. S.

[We have not seen such a defect. Have any of our correspondents who are experienced in gelatine emulsion? Is our correspondent certain that the plates had not commenced to frill? Possibly the film had got loosened, and hypo may have lodged underneath.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF BERLIN.

At the meeting of the 15th May last, Herr C. BRASCH in the chair,

The first communication of importance was a paper by Herr J. KOLK on the "Cyanotype Process and its Significance in Photography." The speaker described briefly the various photo-tracing processes from aniline printing up to the more modern cyanotype or iron process, with his own improvements of the latter. Some of the specimens of his works which he submitted to the meeting showed the extraordinary delicacy and purity which might be attained by his process, and were received by the members present with every sign of a lively interest. More especial attention was excited by the blue opaque negatives, and the transparent positives with half tones on glass paper. It had always been previously imagined that it was impossible to produce by means of iron salts, negatives from which any required number of positives could be taken, in consequence of the blue of the precipitate formed not being opaque to actinic light. In the process of Herr Kolk, however, this precipitate has a deep blue-black colour, and is so opaque that the positives taken through them render dark, blue-black lines on a perfectly white ground. For professional photographers the transparent positives on glass paper were of great importance, as they are in the highest degree transparent and rich in detail, and when the proper kind of paper is used they are quite free from any sign of graining. Several important improvements have also been introduced by Herr Kolk into photo-lithography. As illustrations of these improvements, he exhibited two photo-lithographs, one prepared by himself, the other by one of the local photographers. In the first of these the drawing was perfectly clean and sharp, though retouching had not at all been resorted to; in the other, notwithstanding that the stone had been worked up by a professional lithographer for more than five hours, the finer portions were completely spoiled by the smudging of the lines.

Herr Kolk also introduced the subject of his discovery "The Production of Negatives in the Camera by means of Glass-paper," and his remarks were listened to with manifest attention. He claims for this method, especially, the advantage that the operator is able to control by ocular examination the progress of the development, though, of course, there must

be always some doubt as to how far the negative goes back in the fixing bath. It was thought, however, that experience of the gelatino dry plate process will be a guide as to the length of exposure, and, independently of that, the extraordinary cheapness and ease in manipulation of Herr Kolk's method are such as to recommend it strongly to notice.

Herr F. WILDE, of Görlitz, next gave some information about his various kinds of dry plates. As regards his positive plates, he assured the meeting that nothing further was necessary by his method than to place the picture, after a powerful over-exposure, in a solution of soda, and afterwards to wash it well. It had been objected by some of the members that in this process a gold toning was necessary, but Herr Wilde again explicitly asserted that there was no occasion for any toning, in which he was corroborated by several of the members present who had tried his plates. These plates he stated to consist of a combination of collodio-chloride of silver with gelatine, however paradoxical it might appear to have in a state of mixture an aqueous solution of gelatine and an alcoholic one of collodion. It must be confessed, however, that the mixture can only be kept for a short time in a fluid state, and was very liable to coagulate, for which reason plates ready for use could only be delivered, and not the collodion necessary for preparing the positive plates oneself. The sensitiveness of the collodio-chloride of silver and gelatine plates is far from being as great as that of gelatino-bromide plates, but then the former are used for quite a different purpose—the production of transparent positives. In this case, too, no development is required, though all other chlorides of silver plates must be developed. Exposure in the frames takes about a couple of hours in proportion to the intensity of the negative and the strength of the light; it may even extend to a whole day. The proofs, when taken out of the frames, are laid for from five to six minutes in a 10 per cent. solution of soda, and afterwards only require to be rinsed. When finished, the tone of the negative is an agreeable brownish-yellow, which acts capably in enlarging. Herr Wilde exhibited to the meeting some of his transparent positives by means of a new and improved siccoticon of his own construction, and very lively discussion arose on the comparative merits of enlargements by the silver chloride and by the carbon processes. On the whole, the sense of the meeting was decidedly in favour of Herr Wilde's method, for the simplicity and ease of the manipulations in the silver chloride process more than counterbalance the advantage which carbon possesses in giving greater sensitiveness. Herr Wilde also made some remarks on his gelatine dry plates, and on this subject Herr Brasch observed that after for some time using oxalate of iron and potassium developer, he had fallen back on the alkaline and pyro method. Some of Herr Wilde's dry plates were handed round at the meeting, and called forth a general opinion that their brownish-yellow tone must be of great advantage in copying.

At the next meeting—the last before the recess—held on the 5th of June, the chair being occupied by Herr BRASCH,

Herr H. JOOP, referring to the method of producing negatives on glass paper described by its inventor, Herr Kolk, at the former meeting of the Society, demurred to the statement then made that it was possible in that method to control by examination the progress of development. According to Herr Joop the image of the object to be taken is seen on the focussing plate, and afterwards on the sensitive glass paper, in all the brilliancy of colour of the original. But the blackening of the paper produced by the action of light is so far concealed by the colours of the image thrown by the objective that the eye is unable to observe and estimate the amount of alteration that has been effected.

Herr E. DUBY maintained that observation of the development of the image could be readily effected from time to time by holding a ground glass plate in front of the objective, which would prevent the formation of the optical image, and yet allow sufficient light to penetrate into the camera to allow of the existence and progress of the chemical image being controlled.

Herr KOLK also urged that the power of controlling the development of the image had never been put forward by him as an especial advantage of his process. The principal advantage that he claims lies in the ability to dispense with the development, and the consequent simplification of the manipulation.

A communication to the Society on the subject of two photographic novelties lately introduced to public notice was then

made by Herr E. DUBY, who in conjunction with Herr C. Suck had undertaken some experiments with these new processes. The first of these is a patented process by Herr F. Sandtner, of Tetschen, in Bohemia, for the production of negative plates on paper. It appears to consist in coating glass plates with white wax or paraffin, and then stretching on the coat tissue or tracing paper; on heating the plate, the paper absorbs the wax. By cleaning the back with spirit, and coating the edges with a varnish of shellac, the paper becomes a water and airtight support for the collodion film, which can then be treated in the usual way to obtain a photographic negative. The examiners, however, were unable to report very favourably of the process. They found that the collodion could with difficulty be made to flow over the wax paper surface, and that it left a wavy and cloudy film. It required considerably longer time to sensitise than an ordinary collodion plate, and inclined to repel the silver bath, so that when taken out of the bath it appeared as if covered with a number of minute oily drops. In developing, these defects manifested themselves to a much greater extent, and the plate appeared completely reticulated and ragged. Another inconvenience noticed by Herren Düby and Suck was the excessively long time required to dry by the plate and its coating of varnish. If, however, a plate could be obtained free from the first two defects, it had the advantage of giving a film which could with ease be drawn off the glass, and which is so thin that it could be copied from either side with equal sharpness. The second novelty on which Herren Düby and Suck reported is the collodion paper of Herr Raethel, in Flensburg; on this they had taken several prints which were submitted to the meeting. These prints exhibited several excellences, but also a great want of detail in the shadows. Pieces of the paper were distributed to the members present for subsequent trial.

PHOTOGRAPHIC SOCIETY OF FRANCE.

At the meeting of the 6th of June the chair was occupied by M. DAVANNE, President of the Council.

The only subject of interest brought forward, not alluded to in our French Correspondent's account of this meeting (see PHOTOGRAPHIC NEWS for 13th June, page 283), was an extract from M. L. Monck's treatise on "Printing in Fatty Inks," describing a method of purifying gelatine. This method is due to M. Stinde, and as it succeeds so well in the fatty ink processes, it is hoped it may be of equal efficacy for emulsions. The gelatine is cut into strips and put to soak in pure water, which must be two or three times changed at half-hour intervals. When swollen up and drained, it is placed in a water bath and heated till it dissolves. To each quarter litre of the solution is added the white of an egg diluted with twice its volume of water, and shaken up with five drops of ammonia; this mixture is then well whipped. Acetic acid diluted with 250 times its weight of water is then added drop by drop to the gelatinous liquid, beating it each time, until a piece of litmus paper dipped into it gradually turns red. The whole is then brought rapidly to the boiling point, stirring it all the time with a rod, and kept boiling for three minutes. The gelatine is then filtered through paper, care being taken to keep the filter hot, when the liquid ought to pass through quite clear. When this is completed, the gelatine is poured into china dishes, and allowed to set in a place free from dust; so soon as it quite dry it is cut into small pieces, and put to soak in distilled water for forty-eight hours, care being taken to change the water three or four times. After again drying, the gelatine is put away to be used as required. M. Leon Vidal and Dr. Van Monckhoven, in their works on carbon photography, both agree that fatty matters contained in the gelatine prevent the formation of smooth films, and the latter recommends that the gelatine should be purified by washing it in soda, and dialysing.

The next monthly meeting of the Society was held on the 4th July, M. PELIGOT, Member of the Institute, President of the Society, in the chair.

The SECRETARIES gave a resumé of the contents of the foreign journals. Among these was a communication made by Mr. J. D. Dames to the Pharmaceutical Society of Great Britain, on the action of chloroform as an antiseptic when added in small quantities to vegetable infusions. Mr. Dames thought that this discovery could be applied for the purpose of preserving solutions and organic substances which were liable to decomposition, and some of which are used in photography.

M. CHARDON, however, was of opinion that chloroform ought not to be added to sensitive preparations of silver, as, under conditions not yet understood, that substance produced an injurious effect.

Herr HUSNIK had recommended the Photographic Society of Vienna to use a solution of mercury bichloride in potassium iodide for intensifying negatives of line drawings. The negative is first of all taken by the wet process, using a collodion containing only iodides, and a bath of iron, to which some sugar has been added. According to the intensity of the negative thus obtained, recourse must be had to one of the following methods:—If the image is sufficiently vigorous, it is washed and fixed by sodium hyposulphite; but if the exposure has been too short, it must be intensified with pyrogallic acid before fixing. Sometimes a simple solution of mercury bichloride suffices for obtaining the required degree of intensity; but if still greater intensity be desired, a solution of the mercury bichloride in potassium iodide must be used. This solution is made by pouring one of potassium iodide into that of mercury bichloride until the red precipitate formed is re-dissolved. The method here described is really a very old one. In the year 1866 M. Ommeganck had recommended the same solution, which was at that time known by the strange title of *Eau de Patako*, with the addition, at the moment of using, of a few drops of gold chloride. Platinum chloride might in that case be substituted with advantage for the gold, as the former would not be liable to produce decomposition.

M. ROGER could not agree with Herr Husnik; he had never been able to obtain good results with mercury bichloride.

M. ANDRA drew the attention of the Society to a circumstance affecting the keeping of collodio-bromide emulsion which he had recently had occasion to observe. Of five or six bottles containing emulsion, made more than a year ago, he found two whose corks were completely eaten away by acid. On removing the remains of the corks, intense fumes of hyponitric acid were disengaged, and the emulsion was found to be in a viscous condition, like that of old pyroxyline hermetically sealed up in a bottle. The contents of the other bottles, prepared at the same time, some of which were corked and others stoppered, showed no signs of acid vapour.

M. PELIGOT thought that the decomposition might be due to the humidity of the cotton used for the collodion, and he recommended M. Andra to take one of the bottles which had not suffered change, to introduce a few drops of water, and then to observe whether the conditions of decomposition would not be promptly set up.

M. STEBBING mentioned an accident that had happened to some of his gelatine plates, which, after a heavy thunderstorm, were found to be covered with spots of mould, and were consequently spoiled; he inquired whether there was any means of avoiding the recurrence of this accident. M. Peligot believed that salicylic acid added in small doses might have the desired effect.

Mr. CHARDON communicated to the Society a method of preparing a substitute for ground glass plates by means of gelatine containing barium sulphate in a state of suspension. What he uses, in fact, is an emulsion of the salt in gelatine flowed over a glass plate. He employs two formulæ

(1.)	Water	100	c. c.
	Barium chloride	6	grammes
	Gelatine	5	"
(2.)	Water	100	c. c.
	Sodium sulphate	15	grammes
	Gelatine	5	"

In each case the salt is first dissolved in the water, then the gelatine is added and dissolved over the water bath. When the two solutions are complete, they are gradually mixed together and well shaken; by double decomposition the barium sulphate is obtained suspended in the gelatine in a state of fine sub-division. Before coating the glass plates with this emulsion it must be filtered. Previously to being coated, the plates must be washed and dried, and then laid for some time in a two-per cent. solution of tannin; they are then again washed and finally dried. As the gelatine sulphate of barium becomes more transparent in drying, it is necessary to ascertain by a previous trial what amount of the emulsion to use, and if the result should be that the layer is too mat, it can be rendered clean by varnishing it with amber dissolved in benzine.

M. LEON VIDAL described a contrivance of his own for enamelling the cameo of a photographic portrait while the rest of the mount is kept dull. He takes a glass plate on to which he

glues a piece of thin zinc plate corresponding in size and shape to the opening of the cameo press. All the surface of the plate left free is then roughened with emery, and the zinc is then removed; thus a plate clean at the centre and roughened at the sides is obtained. Such a plate is then used for gelatinizing the prints, taking care that the oval or rectangle in which the portrait is taken shall coincide with the clear space on the glass. The effect thus produced is most satisfactory.

Talk in the Studio.

GELATINE.—Gelatin, it is said, has a peculiar action on gum; if gum be added to gelatin, and the mixture sensitized with ammoniacal potassium bichromate, the behaviour of the latter substance is very little altered by the addition of the former. Its solubility in hot water is somewhat increased, and to obtain the same degree of insolubility for the image as with pure gelatin the exposure must be longer. But if the mixture be acidulated with acetic acid, the film after exposure and desiccation is less soluble than one consisting of chromated gelatin only with acetic acid. Gum, therefore, renders an acid solution of gelatin less soluble, and the reason for this is believed to be that gluten and arabic acid form a compound solid only with difficulty. Borax thickens a gelatin solution, and the alkaline reaction of the same substance tends to render the chromated gelatin more insoluble. Calcium nitrate gives to gum an enormous power of adhesiveness.—*Scientific American.*

NEW FUEL AND LIGHTING.—The following extraordinary story, which reads much like a hoax, has been published by the *Athenæum*:—"A correspondent has sent us a startling letter from Miss M. Betham-Edwards, from which we give an extract:—"I send you the following particulars of a recent scientific invention, just patented, and destined, without doubt, to play a very important part in our economic history. I think it must be regarded as a solution for once and for all of the great coal question, or rather fuel question, not only among ourselves, but abroad. M. Bourbonnel, of Dijon, the celebrated lion and panther slayer, lighted upon the following discovery by hazard, and after six years' persistent investigation brought it to entire 'workable' perfection. He discovered, by means of two natural substances, inexhaustible in nature, the means of lighting and maintaining a fire *without wood or coal*; a fire instantaneously lighted and extinguished; a fire causing no dust, smoke, or trouble; a fire costing one-tenth at least of ordinary fuel; and, what is more wonderful still, a fire the portion of which answering to our fuel is everlasting, that is to say, would last a lifetime. M. Bourbonnel's invention comprehends both stove and fuel. The fires could be on the minutest scale or on the largest. They would be used for heating a baby's food or for roasting an ox. Being lighted instantaneously, they will be a great economy of time. M. Bourbonnel at once patented his invention, and a body of engineers and savants from Paris visited him and pronounced his discovery one of the most remarkable of the age. He has had several offers for the purchase of the patent in France, but wants to sell it in England, his own occupation being in another line. Any English gentleman or firm wishing to see his fires and stoves could do so by writing to him a day or two beforehand. His address is M. Bourbonnel, Dijon. . . . I have seen these fires and stoves. There is no mistake about the matter. It is as clear as possible that here we have a perpetual and economical source of fuel. Two hundred years ago the discoverer would have surely been burnt as a wizard."

To Correspondents.

OLDHAM & ANGLE.—Clean zinc clippings placed in an old fixing bath ought to precipitate the silver in a state of metallic powder. Why it has not done so in your case we cannot guess. Before wasting the clear solution you drew off, did you test it to see whether it contained silver? If from some cause—possibly the zinc not presenting a clean metallic surface—the silver was not precipitated, it would remain in the clear solution which had been thrown away.

REFINER.—Burn the cuttings slowly in a suitable vessel like an iron mortar. Then place the ashes in a crucible with an equal weight of a suitable flux, say carbonates of soda and potash in equal parts. Then apply a suitable heat.

FATUOUS.—A correspondent with this signature sends us a long letter apparently for publication in our correspondence column. As it deals with an individual trouble rather than one of general photographic interest, we cannot with propriety occupy that space with its details. We will make some extracts and comments here. He wishes to ask whether there is any protection for assistants against studio managers who discharge them at a minute's notice on Saturday with the bare week's salary they have worked for. "Two or three years ago a certain youth, in reply to an advertisement in the *Telegraph*, appeared before a well-known photographer. The photographer seemed pleased, the youth was engaged, and received eight shillings per week, with the promise of an increase when he got accustomed to his duty. In course of time he did get accustomed to his duty, but did not receive the promised increase until he remarked that it was high time he had more salary. Consequently, he received one shilling more, and a good deal of abuse from the operator into the bargain. Things went on in this way until one unlucky day the father of this unfortunate youth departed this life, leaving a wife and six children to mourn his loss. The family was of course reduced to poverty, and the youth applied for another rise; he got one, a shilling and a shift to another branch, where he did all the drudgery and assisted the operator. However, he became a good retoucher. His employer, discovering this, by way of a little encouragement raised his salary to one pound sterling, and sent him about a hundred and twenty miles into the country under a highly intelligent business-like manager who was in blissful ignorance of the art. The youth stayed in this place nearly a year, and would have stayed longer, no doubt, had not that highly intelligent manager cut short his career at that establishment, by kicking him into the street one Saturday, with no money in his pocket but the week's salary he had worked for—and out of which he had to pay two weeks' rent and railway fare to London—all because he did not like the position in which he sat to retouch. Dear Mr. Editor, will you be kind enough to tell me through your journal whether that youth cannot claim another week's salary. He has applied three times to the head of the firm without avail." The case of our correspondent appears a hard one; but his grievance is in no wise essentially photographic, nor are we a fitting authority to decide it. According to law, a servant cannot be dismissed summarily without notice or wages in lieu of notice, unless he has been guilty of some sufficient fault, such as refusing to do his work or to obey his employer's reasonable commands. His only remedy is a legal one, to which we cannot help him.

J. JONES.—We do not know whether any of the artists to whom you refer will produce an enlargement from a print. If they do, it will necessarily cost more, and be less perfect, than if made from a negative; inasmuch as the print must be copied and a negative produced before an enlarged collodion transfer can be produced. Prices quoted doubtless refer to enlarging from a negative.

BACH.—You will find full details of the same or a similar process described by Mr. Pumphrey in our YEAR-BOOK for 1879 on p. 144.

B. B. L. asks if it is not a simpler and better plan to produce an enlargement on sensitive paper than to be at the trouble of producing an enlarged negative, especially if few copies are wanted. It is undoubtedly a simpler plan, but not nearly such an efficient one. An enlargement made on paper from a small negative is almost invariably a developed print, which is generally flat, sunken-looking, and dull compared with a print taken direct from a negative in the pressure frame. A sharper, more delicate, and more satisfactory enlargement can always be obtained by making an enlarged negative, and printing direct from that. Certainly the superiority of the print is worth taking the greater trouble.

M. L.—Skillfully managed, a Daguerrotype will yield an excellent copy. The portrait you describe will require cleaning first. Make a weak solution of cyanide of potassium, a piece of the size of a hazel nut in half a pint of water. First see that the surface of the plate is not greasy, repelling the flow of water. This is very necessary, as it frequently happens that such portraits have been removed from their mounts and handled. If water do not flow freely over the surface, wash it with alcohol until it flow freely, then rinse thoroughly with water. Now treat it with the cyanide solution, and watch it carefully. As soon as the varnish stains are removed, place it under a tap, and let the water run freely, otherwise the cyanide may injure the image. Finish the rinsing with distilled water, and dry by applying the flame of a spirit lamp at the back of the plate. In copying, proceed as with an ordinary print, taking especial care to avoid reflections from the polished surface of the plate.

ECONOMIST.—The best use to which you can apply a very old sample of collodion which gives a rotten, powdery film, but is not very insensitive, is to mix a little with a new tough sample, which will be greatly improved by the addition.

CHROMATOPHILUS.—In our next. Several correspondents in our next.

The Photographic News, September 12, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AND PHOTOGRAPHIC EQUIPMENTS IN WARFARE.

No better evidence of the importance with which the British Government regards photography as an aid to military science is afforded than that displayed in a recent publication giving a complete detail of warlike stores which has just been issued by the Secretary of State for war. It is entitled "Priced Vocabulary of Stores used in Her Majesty's Service," and to those interested in the matter we may mention that it is to be obtained of any bookseller for the sum of three shillings. For the most part, no doubt, it furnishes but sorry reading, but still there are many who like to know how much a big gun costs, or what is the price of the orthodox "gaiter-button." But photographers will certainly be interested in the portion appertaining to "Photographic Implements and Materials forming the Equipment of a Photographic Waggon." It must be borne in mind that modern armies are furnished with necessities and apparatus that were quite unknown to our forefathers, and a well-equipped force now-a-days carries with it the means for erecting telegraphs, surveying and making roads, printing and lithographing documents, mining and diving, laying down railroads and blowing them up, and last, if not least, the wherewithal to make photographs. Every army corps, which consists in the British army of some 36,000 of all ranks, is not complete unless it numbers among its *personnel* a sergeant-photographer and assistants, and among the *matériel* a photographic waggon and a very complete list of stores. To judge by the *Vocabulary*, this military photographic outfit is very sound and substantial, and calculated, therefore, to excite the envy of many a brother in the craft. That it is costly goes without saying, for only good apparatus and sound workmanship could be trusted to endure the vicissitudes of a campaign. To begin with, the photographic waggon itself, drawn by a pair of stout army horses, is an object to admire. It is entered by a door from behind, and, under ordinary circumstances, presents the appearance of a small and compact travelling office, provided with seats and well lighted. In these circumstances it fulfils all the conditions of an ordinary workroom, where prints can be toned and fixed, and trimmed and mounted without difficulty. To convert it into a dark room, it is only necessary to adjust the coloured glass windows and make use of a screen if necessary. There are shelves and cupboards, trays and stands proper to manipulation, to the storage of baths and chemicals, all made in the most substantial and durable manner. In fact, when we state that the price of the waggon complete is no less than £200, our readers will readily understand that a very perfect carriage must be at hand. We shall not go through the various items that are contained in this waggon, for, as we have said, anyone who desires the information can obtain it, and much more besides, for a few shillings. Still our readers will probably like to know what sort of apparatus and to what extent photography is employed in the army. In the way of cameras, for instance, we find the soldier-photographer is provided with three, two of which are capable of securing any size plate up to 12 by 10, while the third is a small hand camera provided for taking 7½ by 5 pictures. The camera-stands chosen by the War authorities are marked "Paget's Pattern," and these also are three in number. So that in case of accident the photographer has more than one string to his bow. Of collodion, the supply provided is ten pints of plain and ten of prepared, while of pyroxyline and alcohol and ether there are also certain quantities, to permit of further supplies of collodion being made. The lenses provided for service in the field are six in number, viz., a pair of stereoscopic lenses

for small rapid pictures, two rapid rectilinears of Dallmeyer for 12 by 10 and one for 7½ by 5 plates, and one wide-angle rectilinear, also of Dallmeyer, for 12 by 10 and 7½ by 5 pictures. A cone for copying is not forgotten, and of 12 by 10 plates "crown glass, thick, polished, the supply taken is a gross, and 7½ by 5, half as many. Besides the waggon itself, which can be employed as a dark-room, there is provided a box tent, "Ahney's pattern," together with a supply of tammy and fitments for the improvising of dark chambers. Of course provision is made for the employment of dry plates, and double backs for dry plate box are not forgotten. Three dipping baths, one of ebonite and two of glass, form part of the equipment, and eight large and eight small printing frames. A ream of aluminized paper is supposed to furnish sufficient material for printing, and the amount of uirtrate of silver deemed sufficient is ten pounds. A copper still with condenser allows the soldier-photographer to make his own distilled water if he happens to fall short of that commodity, and altogether, as we have said, the equipment is of a most perfect character. Several such equipments are kept in the military stores ready for use at any moment, so that when war is declared no delay shall occur in providing photographic necessities. As to the uses to which photography may be put in the field, these have by no means been exhausted, albeit many Continental nations have availed themselves of the art. The first application of the camera in warfare dates from the Crimean war, when two young officers, Ensigns Brandon and Dawson, were sent out from England by Lord Panmure, after they had in the first instance received proper instruction from Mr. Mayall. Some of the work of these officers is still in existence, Mr. Mayall having presented several of the pictures which came into his hands to Mr. Baden Pritchard, of the General Photographic Establishment of the War Department. In the Franco-German war of 1870, both the Germans and French made use of photography in the field. The Prussians organised a corps of photographers under the command of a captain and lieutenant, and sent them to Strasburg, to help in the reduction of that fortress. Many valuable measurements and reconnoitring pictures were taken before Strasburg by the camera, and when that fortress fell the military photographers were transferred to the Paris lines of investment, there to perform further service. On the side of the French, apart from the invaluable aid photography rendered in producing microscopic despatches for transmission by pigeon to the besieged capital, photography in the hands of the French engineers did much good service. Plans and maps were prepared and copied by its agency, and indeed in the military topographical department of France the camera has for years past held a prominent position. The Commandant Laussedat was one of the earliest to foresee the valuable aid of photography in war, and it was under his auspices that M. Auguste Chevalier developed his invention, the *planchette photographique*. The photographic plane-table is still employed by the French War Department as a rapid means of surveying, and had it not been for M. Chevalier's premature death, there is no doubt that further applications of photography to warfare would have been forthcoming. The Emperor himself ordered that every facility should be given to M. Chevalier to carry out his experiments on a large scale at Vincennes, that gentlemen having pledged to obtain with the plane-table the following results: 1. By employing two proofs obtained with the instrument, to regulate in the most certain manner, during the night-time, the direction of fire against an enemy's works, as likewise the angle of reflection of the electric light to be used for illuminating the same; 2. In like manner to regulate the convergent fire of one or more batteries as well during the night as during the day. Our readers will thus see that photography and war are likely in the future to see a good deal of one another.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

[FROM OUR SPECIAL CORRESPONDENT.]

THE forty-seventh Annual Exhibition of the above Society commenced on Tuesday, September 2nd, and remained open during the week. At Falmouth it may almost be called a gala week, for the West visitors flock hither in thousands, and take a lively interest in its proceedings; and it is my opinion that a Society of this sort serves as a pattern for other societies. During the Exhibition occasional lectures are delivered in the evenings upon various subjects. Of late years the Photographic Department has been a very important feature, and many West country photographers avail themselves of being able to view the works of others without the long journey to town, which is a boon to many.

The Rev. Canon Rogers (of Grennock) gave the opening address, in the place of Professor Taylor, who was unavoidably absent through ill-health. The rev. gentleman spoke in high praise of the exhibits in the Photographic Department, mentioning several of the exhibits, especially those of Messrs. Wratten and Wainwright, also the platinum prints of Mr. Willis; he also referred to the charming productions of Mr. Andrew Pringle, and the Arctic photographs of Mr. A. J. Grant. Mr. Payne Jennings also came in for some very eulogistic remarks. He also called special attention to the new department connected with the photographic, and that was the Photographic Appliance Department, including the magic lantern, which might, he said, almost be termed a photographic instrument, as it generally exhibited photographic productions, and he hoped in future years to see more exhibits generally.

In the evening Mr. R. N. Worth, curator of the Society, gave a kind of lecture on the exhibits; he also alluded in very strong terms to the exhibits in the Photographic Department.

On the following evening Mr. W. Brooks gave some practical demonstrations of the gelatine dry plate process, also Willis's Platinotype process, which seemed to surprise many, to see the prints developed so rapidly one after the other; it seemed quite new to them. The emulsion process was illustrated by the use of a Sciopticon kind of lantern, an exhibit of Mr. J. Middleton, of London, which answered admirably, and seemed to delight the audience immensely. The whole of the experiments went off without the slightest difficulty on the part of the demonstrator, and without a single break for the space of two hours.

The exhibits generally in the Photographic Department were not so numerous this year, due, no doubt, to the general depression and bad weather that have been so prevalent of late; but it was the opinion, I believe, that the general excellence was far above the average. Portraiture fell very short. Mr. W. Gillard had the principal award for a portrait study taken direct on about a 20 by 16 plate, the award being a first bronze medal. The same artist had two other pictures, "Little Bo-Peep," which I did not like quite so well, the background being somewhat too light; his other picture, "The Little Washerwoman," was a fine production.

Mr. Payne Jennings' exhibits have been awarded a first silver medal. It would be superfluous on my part to attempt to say anything about them, his work being so well known.

Messrs. Hills and Saunders, of London, sent a frame of cabinet portraits of children. These were taken in one second in the studio on gelatine plates, and I think I may say that I have never seen their equal. To these was awarded a first bronze medal, and I should think if they could send some larger examples of their work they would obtain a higher award. I give this as my opinion only.

The exhibits of Mr. Willis' platinotype process were

admirable. In my walk round I heard several artists (painters) whom I knew express themselves in very high terms on the extreme delicacy and fine gradation. A second silver medal was awarded to the process.

The Oxford and Cambridge University Boat Race of 1879 were remarkable examples of instantaneous photography, and seemed to create very great interest on the part of the public. These obtained the Society's first silver medal.

Mr. B. Wyles, of Southport, sends some instantaneous (so-called) cattle. Many of them had moved, and were anything but good examples in any way. His studies of trees were very fair; but with more care in their manipulation, I should have liked them better. They were well chosen subjects, and I should like another year to see Mr. Wyles come forward with work that I know he is well capable of doing, which will be greatly benefited by attending to several little points.

Mr. Hazard shows some very fine examples of portraits taken at a fancy dress ball at night by the Luxograph apparatus, which are almost, if not quite, equal to daylight, and, by the judges' report, I find that they were unable to make an award to either him or the Luxograph Company, as they both exhibited prints from the same negatives in several instances.

Mr. F. Hollyer's rustic studies were very fine indeed.

Mr. Nesbit, of Bournemouth, contributed several nice things; but I think I have seen the same subjects some time ago, so need not make any remarks upon them.

Mr. Lenthall, of Reigate, contributes two very fine small interiors, cabinet size, taken on gelatine dry plates. They are fine examples—indeed, a second bronze medal is the award.

Mr. J. Terras has several productions possessing several good qualities.

Mr. H. G. Cocking, of Lee, Kent, sends a group of the members of the South London Photographic Society, an enlargement in carbon, for which a second bronze medal was awarded. He is not himself in the portraits he exhibits. I have seen others of his that I like much better.

A nice group of three ladies by Jas. Russel and Sons, of Worthing, has been awarded a second bronze medal. It is very soft and delicate, and one would never think the other exhibits were done by the same party. I myself think they show want of taste in forwarding such subjects for exhibition. The titles are very stupid, being three pet apes of the same subject, "Study of Expression." Grinning, they might do very well for a country fair for the horse collar business, and I consider them quite out of place at such an exhibition as this. I should advise them to keep a better class of picture.

Mr. J. Milman Brown, I am pleased to see, is again a contributor. I like his picture best, "A Country Road," being full of good feeling and effect.

The finest carbon work in the Exhibition is a frame of three portrait studies, two of them being the undraped figure of a child very artistically treated; a first bronze medal being awarded.

The exhibits of Mr. E. Baker, of Birmingham, are very creditable productions.

The Amateur Department is well represented. Mr. A. Pringle's exhibits are, in my estimation, the finest examples of landscape photography ever produced. R. M. Gordon, Esq., will find in him another Richard in the field: award, a second silver medal. Mr. T. M. Brownrigg sends some fine examples of his work. The photographs by Mr. Grant, being a series of the Arctic regions, has been awarded a second silver medal; they are very fine indeed. Mr. A. J. Daniel contributes some very meritorious productions; a little under-exposed if anything. Mr. Ferneley, of Reigate, has again some of his charming rustic studies, which are known so well. The transparencies of Mr. H. Manfield are very fine indeed; in fact, I have never seen so fine at any exhibition.

The Photographic Appliance Department is a new department, and contains several very interesting things. Mr. G. Hare, for his ingenious changing box, is awarded first bronze medal. The Malden Triplet Lantern, by J. Middleton, second silver medal for perfection of workmanship.

Mr. Keevil's Duplex Improved Lantern was awarded first bronze medal.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

MR. BROOKS' LECTURE ON PHOTOGRAPHY.

ON Wednesday evening there was a good average attendance of visitors to the exhibition of the Royal Cornwall Polytechnic Society at Falmouth. Mr. W. Brooks, of London, lectured on Wednesday evening on "Photography, Past and Present," to a large audience, numbers being unable to obtain admission to the room in which the lecture was given. Mr. George Lanyon, of Falmouth, presided, and snitably introduced the lecturer.

Mr. Brooks, who treated his subject in a pleasing conversational manner, remarked that as photography now made one of the main features of the Polytechnic Exhibition, he thought it might be of interest to try to explain to visitors some of the new processes in this art. Since he was there last, two years ago, important changes had taken place in photography; in fact, it had been almost revolutionised. Gelatine had been substituted for collodion, and by the use of gelatine, exposures were very much lessened. Mr. Brooks then traced the history of photography from its earliest days, dating as far back as 1722, to the present, and gave a retrospective glance at the different actions of light photographically as they were introduced to the world by various experimentalists. He especially eulogised the names of Wedgwood, Sir Humphrey Davy, Robert Hunt, and Scott Archer. Wedgwood received very valuable assistance from Davy in carrying out his experiments, and, indeed, photography would not be what it was at present but for Sir Humphrey and Robert Hunt, who might be said to have been the pioneers in photography. Archer introduced collodion in 1851, and it was strange to say that from that time until 1864 there was very little change in photography. In 1864 a very great discovery was made by Messrs. Bolton and Sayce, of Liverpool, and announced to the world in a paper read in September of that year to the Liverpool Photographic Society. This was the practical beginning of the emulsion process. The lecturer then performed numerous experiments, introducing mechanical appliances such as the changing box, and the spring, pneumatic, and electric shutters for exposing instantaneously. He also illustrated his lecture by making gelatine emulsion, and described it in detail, and gave further illustrations by the use of Mr. Middleton's excelsior lantern, by which he projected images on a screen. Of these the views of the Oxford and Cambridge boat race by Messrs. Wratten and Wainwright, of London, were especially noticeable, and were much admired. He likewise showed the dry plate changing box, a very ingenious instrument, the working of which was fully explained. After some remarks on the various printing processes, Mr. Brooks gave demonstrations of Willis's platinotype process, by which prints were developed in the presence of the audience. He pointed out the undoubted permanency of Willis's process as compared with silver prints, which were more or less injured by atmospheric influences; whereas prints by the platinum process endured the severest tests, even immersion in nitric acid, or the fumes of sulphuretted hydrogen. The lecturer next called attention to the numerous specimens of dry plate photography exhibited on the walls, and particularly called attention to the productions of Messrs. Wratten and Wainwright and Andrew Pringle, and the most perfect productions of portraiture of Mr. Alexander Cowan, and the firm of Messrs. Hills and Saunders, London.

The lecture throughout was listened to with much interest,

and the hearty applause that frequently greeted Mr. Brooks's experiments showed that his efforts were greatly appreciated.

In reply to the chairman, the lecturer said Mr. Willis, a native of St. Austell, was the inventor of the platinum process.

Mr. Harry Tilly moved, and Mr. Thomas Olver seconded, a hearty vote of thanks to Mr. Brooks, and both of them expressed the great pleasure it had given them to hear the interesting and instructive lecture that gentleman had delivered. The motion was carried by acclamation, and the proceedings terminated.

PRINTING WITH COLLODIO-CHLORIDE OF SILVER EMULSION.

IN compliance with the request of several readers, we reprint some formulæ and instructions for working with collodio-chloride of silver, no instructions having appeared for some time in our pages.

Mix three stock solutions—

No. 1.—Nitrate of silver	1 drachm
Distilled water	1 "
No. 2.—Chloride of strontium	64 grains
Alcohol	2 ounces
No. 3.—Citric acid	64 grains
Alcohol	2 ounces

Now to every two ounces of plain collodion add thirty drops of No. 1 solution, previously mixed with one drachm of alcohol; then one drachm of No. 2 solution gradually, shaking well at the same time; lastly, half a drachm of No. 3 solution. In a quarter of an hour it will be fit to use.

M. de Constant has found that prints are much improved if the sensitive paper or glass is fumed with ammonia; and Dr. Monckhoven points out that fuming prevents solarization or the formation of a light brown by over-printing.

OPAL GLASS.—Flashed patent plate answers best. It should not, under any circumstances, receive a preliminary coating of albumen, which is a source of fading.

Preparing the Plate.—The plate should be quite clean. We have found that running an edging of dilute albumen all round, and allowing it to dry before coating the plate, prevents the loss of the film in toning, fixing, &c. After the film of collodio-chloride has set, we finish drying before a bright fire, taking care that the thick edge where the plate was drained is quite dry, or the negative will be injured. The plate is left a few minutes to cool, and is then placed in the printing-frame.

Printing.—It is better to use one of the many printing-frames made for the purpose, which permit the progress of printing to be examined without risk of movement. The printing should be a little deeper than is required for albumenized paper.

Toning, Fixing, and Washing.—If the edging of dilute albumen have not been used, an edging of a solution of wax should now be run round the film, and this will prevent it slipping or becoming loose. An old and dilute acetate bath answers best; but any toning bath may be used, provided it is not too active, as in some cases the image tones in a few seconds to a slate colour, and is spoiled. It is generally important that the bath should be weak and old. A bath of hypo and gold also answers well. Fix in a solution of hypo three ounces to a pint of water. Five minutes' immersion is generally sufficient. Wash for five minutes under a tap. The prints should not be toned deeper than a warm brown or purple, as they lose no depth in the hypo, and are blacker after drying.

Collodio-Chloride made useful for Printing on Ivory.—No modification of the formula is required; a sample of collodio-chloride which works well on paper or opal glass will give admirable pictures on ivory. The prepared ivory is coated with collodio-chloride, and, when dry, is printed, toned, and

fixed in the same manner as a picture on opal glass. The film adheres with sufficient tenacity to render any edging of varnish unnecessary. A more perfect washing, to remove the hyposulphite, is necessary than with opal glass, because of the more absorbent character of the ivory.

We subjoin condensations of an article by Professor Krippendorff on collodio-chloride.

Professor Krippendorff describes his operations in the preparation of what he styles "Simpsonstype" paper as follows:—(1) Two grammes of nitrate of silver dissolved in two grammes of distilled water. (2) Half a gramme of chloride of calcium dissolved in eight grammes of alcohol (ten cubic centimetres). (3) Half a gramme of citric acid dissolved in eight grammes of alcohol.

Of solution No. 1, thirty-six drops are taken and added to thirty-four grammes of hot alcohol, together with one and a-half or two grammes of gun-cotton. After shaking the mixture, there are added thirty-six cubic centimetres of hot ether, agitation being again renewed until the final dissolution of the cotton. Before the collodion cools, four and a-half cubic centimetres of solution No. 2 are added during constant stirring, the mixture being kept in the dark room, and finally a like quantity of solution No. 3.

A quarter sheet of thin polished card or gelatinized paper is now bent at the margins to form a tray, and coated. Ordinary sized or gelatinized writing paper may also be successfully employed. It is stretched out to dry by means of pins or clips.

The printing is conducted in the same way as with albumenized paper, the deep black being allowed to bronze before the prints are withdrawn from the pressure frames. The tone of the pictures varies from violet to indigo blue, the former being due to papyroxyle, and the latter to ordinary pyroxyline. After printing, the pictures are placed in a washing bath; the water employed in this bath—which is simply common spring water—should be renewed every two or three minutes, as the prints will otherwise assume a yellowish tint, and become spoilt.

For toning and fixing, another set of three solutions must be prepared thus:—(1) Forty grammes of hyposulphite of soda dissolved in a dish containing one hundred and fifteen grammes of distilled water. (2) Two and a-half grammes of acetate of soda dissolved in fifty-five grammes of distilled water. (3) One gramme of chloride of gold dissolved in fifty grammes of distilled water.

Of solution No. 3, two and a-quarter cubic centimetres are put into a dish with solution No. 1, and afterwards solution No. 3, and in this mixture the pictures are laid in succession. They become, in the first instance, yellow, then brown, purple, red, and finally black. After half an hour the operation is finished, and the prints rinsed one by one, they being subsequently placed in a porcelain dish of water. By immersion in warm water the film may be removed and transferred to fresh paper which has not been in contact with hypo.

The best and simplest method of applying film to a second support is perhaps the following one:—The film is lifted from the water by means of a glass plate, and coated with a solution of gelatine (one part of gelatine in fifty parts of water); a sheet of fresh chalk or lithographic paper of the requisite size is then pressed upon the image, and a corner of the latter carefully lifted in contact with the paper, by which method the two surfaces may be perfectly brought together into contact. The picture is now dried between two pads of filter-paper, without, however, proceeding to press it in any other way; and to prevent any risk of tearing the film—an accident which easily happens—the surface may be coated with an application of positive varnish.

In regard to the value of Simpsonstype pictures, Professor Krippendorff sums up as follows:—Permanence, beauty, simplicity of preparation, are all on the side of these productions when compared with prints on albumenized paper. "In the first place," he observes, "the costly sensitizing bath is dispensed with, and, in like manner, the time-taking operation of silvering the albumenized surface; instead, the

paper is simply coated with collodion, the operator enjoying the palpable advantage of being able to prepare at one time sufficient sensitive material to last him for a week. There is also the saving effected by rendering unnecessary the tedious process of washing, and a continual flow of fresh water, which is invariably required in the manipulation of albumenized prints. The rapidity of production is another point to be duly considered, for it would be possible, in working the Simpsonstype, for customers from the provinces who come up to town for a few hours only to receive the same afternoon copies of the photographs taken in the morning. These advantages, together with the circumstances that transparencies are by the process easy of preparation, and that negatives may, in the same way, be multiplied, should certainly secure for the collodio-chloride method an increase of attention on the part of photographers."

Mr. George Bruce, of Dunse, who has been very successful in the use of commercial collodio-chloride paper, tones and fixes as follows:—No. 1. In fifty ounces of distilled water dissolve sulphocyanide of ammonium, one ounce two drachms, bicarbonate of soda, twenty grains. No. 2. In fifty ounces distilled water dissolve five or six tubes chloride of gold.

Fixing Bath.

Hyposulphite of soda	5 ounces
Distilled water	30 ounces

"To prepare a bath I measure out the quantity of gold solution necessary for toning the batch of prints on hand, put it into a bowl with plenty of powdered chalk; then take another basin with hot water; place in it the vessel with the gold solution, allowing it to remain (say) from ten to fifteen minutes, till the water and the solution are nearly of the same temperature. I then remove the gold solution, let it stand till it cools (or, if I am ready to tone, mix it with an equal quantity of the sulphocyanide of ammonium solution), and then filter. I fix in a strong solution of soda, keeping the prints in the bath from two to three and four minutes; by so doing I secure purer whites than I would get by fixing in a weaker bath."

AMATEUR PHOTOGRAPHY.

BY CAPTAIN ABNEY, F.R.S.*

Now as to where to go. The localities are infinite. "Bits" too insignificant (perhaps too difficult) for the sketcher are often gems for the photographer. Take two examples which we have before us. In the first, the day is evidently one of summer's best, and the student of nature has come across a wayside pond. The wind has blown the duckweed to one corner, and in the mirror-like surface the reflections of the trunk and branches of an ash are broken by a couple of cows which are cooling their limbs in the water, and seeking shade from a powerful sun. A rough-looking hedgerow, with its bottom of long grass and flowerets, helps to make the picture, whilst the round boulders immediately in front give the necessary force to the foreground. In the second we have an old cottage with its broken down gables and quaint lattice windows, and an octogenarian occupant has been made to "sit" naturally in the porch, forming a most suggestive picture. "Bits" such as these are to be met with close to London or any of our provincial towns, and many a spare afternoon has been spent by ourselves and other amateurs in a friendly art competition over them. If the amateur, however, should wish to make a more extended tour, there are many localities which will give exquisite subjects for the camera. Perhaps there are no two spots from which a more varied selection can be made than Lynmouth and Bettws-y-Coed. The Devonshire village is on the sea, and the cottages lining the road leading to the roughly-formed pier, with its tower head, form pictures from almost every point of view. By walking some

* Continued from page 424.

two miles inland, along the valley of the Lyn, the pedestrian plunges at once into the "waters meet," where numberless varieties of tree, rock, and fern are mirrored in the stream which runs through it. The Welsh valley is more extended, but the scenery is totally different. The ivy-clad bridges of the village, the river running between groups of magnificent trees, and the moss-coloured rocks that form part of its banks, are subjects on which an innumerable number of changes may be rung, whilst a ramble up the Lledr Valley will give him views of hill scenery which are almost unique for beauty in their combination of water, rock, distant mountains, and trees. It may safely be said that where there is a stream or a lake, there is an opening for photography. Killarney, the Cumberland lakes, the Thames, the Wye, are all localities in which a pleasing photograph is more than a probability, whilst if we journey up to Scotland, and can make our way to Loch Maree or Skye, we have scenery which is totally different in character to anything in England or Wales.

Now as to how to make the best of a picture. It is almost impossible to give rules in a short paper, and were they laid down, in all probability it would be found that the most successful pictures are made by those who know *when* and *how* to break through them. There is a certain amount of practice required in choosing a subject, for though we may look on the focussing screen of our camera and see upon it a view that in chiaroscuro seems perfect, yet when photographed it may prove unsatisfactory. The reason is that the photographer, besides observing the ordinary light and shade, has to translate the colours into blacks and whites. Thus dark green will come out black in the print of a photograph, whilst the blue sky will be nearly white; the yellow bracken and the blue-bell which, maybe, add such value to the foreground, will have a totally distinct effect where such translation is made. Hence it is that practice is required to obtain a photograph which shall prove entirely satisfactory to the artist.

Of all the baucs of photographers, however, the worst are the human race. Gentlemen in tall hats, ladies dressed in the height of fashion, or villagers who cannot stand still, will often mar a picture; but by a little persuasion they can generally be made subservient to the photographer, or at all events can be made non-obtrusive. We well remember one quaint village in Kent where we were photographing a "bit." The whole village put on their best garments, and asked us to take their likeness (price no object). Nothing would content them, but they must have their "likeness took." Luckily we had a friend with us who, after we had focussed the subject that we wished to take, skilfully grouped the Darbys and the Joans together in such a way that they were out of the field of view. When thus arranged we quietly uncapped our lens for some dozen seconds, and secured the picture on which our heart was set. A plate of doubtful character was then exposed on the village group, and the lens uncapped. A sitting of a couple of minutes cooled their eagerness; and when they wanted to see the "pictur," their wrath was unbounded on being told that ours were dry plates which had to be "brought out" at home. If one can secure, however, a real rustic, gracefully posed in a country scene, it adds much to the force of the picture. A golden rule to remember is this: either take a photograph of a landscape or of a figure; don't try to do both. If the one is to be the centre of interest, make the other entirely subservient to it; if you don't, the one will spoil the other.

Photographers, be they amateurs or not, are always to a certain extent looked down upon by the world at large, be it gentle or simple; and we cannot close without recording one incident which shows a remarkable and perhaps unique expression of the feelings of the population towards them. One day, near the Pyrenees, we were working at our "trade," on a hot and dusty day, dressed in a common blouse to save our more respectable garments beneath it. We had secured many good views (it was in the days of the old "wet" process), and whilst standing with our camera

over our shoulder, and mopping our forehead with a handkerchief held in hands apparently not too clean, an old peasant woman, who was trudging along the road with her grandchild toddling beside her, stopped in front of us and looked up and down at us. Pity, commiseration, or what you will, seized the heart of this dear old dame, and she put her hand into an old-fashioned pocket, which was well hidden beneath the short skirts of her dress, and pulled out a sou. She advanced to us, held out the coin (which in astonishment we took), muttered, "Pauvre garcon," and trudged along again. That sou we keep; it reminds us of a kindly French heart, and of the estimation in which the followers of the art are held even by the poorest.

PROFESSIONAL BEAUTIES' OCCUPATION GONE.

OUR brilliant contemporary, *Funny Folks*, who is generally in the secret of all political and social news much in advance of its contemporaries, says: "The Queen having signified that she regards with great disfavour the profession of the 'Fashionable Beauty,' it is possible that the pets of the camera will see fit to amend their ways, with the ensuing dramatic result:

ACT I.

SCENE—*Mrs. Langtry's Boudoir.* MRS. LANGTRY, MRS. WEST, MRS. WHEELER, and the COUNTESS OF DUDLEY discovered admiring their reflections in the mirrors which line the apartment.

MRS. LANGTRY. Horrid old creature! If she had eyes like mine, she would not be so ready to withdraw their photographed beams from the poor public.

MRS. WHEELER. No, indeed. It's quite too awful cruel! What will the wretched City clerk do, for example, when he has no longer my sweet nose to cheer him on to brighter days?

MRS. WEST. Your nose, indeed! What does he care about your nose? Unhappy creature! his real loss will be my "large and furry hat." That gone from the picture, he will inevitably perish in the snow-storm of existence.

COUNTESS. I suppose, however, that we do not mean to brave Royal displeasure?

THE OTHERS. Certainly not; and yet—and yot. (*Sighing deeply*). Poor, poor 'Arry.

[*With tears in their bright eyes, the lovely quartette pose themselves afresh as the act-drop descends.*]

ACT II.

SCENE—*Mr. Langtry's Smoking room.* MR. LANGTRY, MR. WEST, MR. WHEELER, and LORD DUDLEY discovered. *They beam on one another, and rub their hands.*

MR. LANGTRY. Well, this is jolly!

MR. WEST. Proper, and no mistake! Her gracious Majesty is a trump, and deserves the thanks of every married man in England. I say, Langtry, how many touting photographers have you kicked to-day?

MR. LANGTRY. Only two; but I smashed the apparatus of another into smithereens.

MR. WHEELER. I've—ha, ha, ha!—I've got the last one who called shut up in the coal cellar at the present moment.

LORD DUDLEY. First-class notion, that. Look here. I'll gladly stand you a hundred of Silkstones to shoot on the beggar's head—I will, bai Jove!

[*Hands over the money. Tableau—the four Husbands do no'ng a solemn saraband of joy and thankfulness round a bonfire of their Wives' photos kindled in the largest spittoon.*]

ACT III.

SCENE—*The Strand.* 'ARRY, TEDDY, and BILL discovered *gazing moodily into a Photographer's window.*

'ARRY. Well, this 'ere is a flowery go, an' no error. Only the Bishop of Runtifoo an' a bilin' o' common haetresses!

TEDDY (*darkly*). Wot's life without West? That's wot I wants to ask you.

BILL (*more darkly still*). Destruction or Dudley's my mo'tor!

[*Teddy and Bill link arms, and move off towards the river with a dread purpose in their eyes.*]

'ARRY (*restraining them*). No, boys, it ain't come to that yet. Foreseeing this dread calamity, I purchased largely; and if you'll jest come along o' me to my drum, you can take your pick o' the latest—shillin' ones half a dollar, cabinets five bob.

[*All eagerly mount suburban 'bus as the curtain falls.*]

THE POWDER PROCESS IN PRACTICE.

ONE of the most charming processes in photography, fascinating alike in practice and in results, is probably more neglected than any other branch of the art: we refer to the powder process. It is certain that some of the most charming sun pictures we have seen have been produced by this process. Its plasticity of application to different purposes is amazing; it is neither costly nor difficult; it is not hampered by patents or restrictions of any kind; it does not require costly apparatus; it permits more artistic control than any other process; and its results are permanent.

We have said it is not difficult, but it is fortunately not easy. It requires patience, perseverance, skill, and experience to secure perfect success. We rather rejoice when a process demands these qualities, as it guarantees the highest success to those most deserving of it. The powder process is not extensively practised, probably because few have given sufficient care to working to become familiar with its beauties.

The powder process is one of the oldest systems of permanent printing. As long ago as 1858, Messrs. Garnier and Salmon presented a paper to the French Photographic Society, describing a process in which paper treated with citrate of iron, and exposed under a cliché, then subsequently treated with a dark powder, produced a print. Citrate of iron, under the action of light, became hard and insoluble, whilst the portion protected from the action of light remained hygroscopic and tacky, so that a fine powder applied to its surface adhered in precisely the degree in which it had been protected from the action of light, so forming the shadows of the picture. Shortly afterwards the same gentlemen competed for the Duc de Luynes' prize with the process modified to something closely resembling the process practised at the present day. Instead of using the citrate of iron, they used a syrup made by dissolving thirty parts of white sugar in thirty parts of water, to this solution seven and a-half parts of bichromate of ammonia and ten parts of albumen being added. This formed the sensitive preparation. Shortly after this a process of producing enamels was patented in this country by M. Jobert, which was based on precisely the same principle; the powder consisting of ceramic colours, which were fired in a muffle, and burnt in. About ten years ago another similar process for paper prints was patented in this country by Mr. Window. The process has, in fact, been forgotten, and revived several times. A few years ago it was revived, and became a favourite process for use in multiplying negatives, to which purpose it was very successfully applied by Herr Obernetter, of Munich. Its adoption by Mr. Faulkner, who showed specimens of marvellous beauty in several recent

exhibitions, obtained for the process much admiration. Probably the most accomplished worker of the process at the present day is Mr. Cowan, of Porchester Terrace, who unerringly succeeds in securing perfect pictures, and, we believe, gives lessons in working the process.

We recently spent a few hours in the dark room of a distinguished London portraitist, watching the manipulation of this process, a few observations upon which may interest our readers. Various substances are available for the support of the picture, but nothing is better or more effectual than opal glass, ground and smoothed, but not polished. The glass in this stage, technically described as "smoothed," possesses a surface like dead unpolished marble. To clean it, a strip of cloth, rolled into a rubber, is dipped into a creamy mixture of chalk and water. The surface is well rubbed with this, and then well washed with clean water flowing from a tap. It is drained, but not dried, and is ready for coating with the sensitive syrup. This is poured on gently, so as to cause it to flow in an even wave over the plate, driving the water before it. The first coating applied is wasted when poured off the plate, as it takes with it the water. The second coating is then applied, and the surplus returned to the bottle. The coating is now dried by the aid of a bright, clear fire, or of the flame of a Bunsen gas burner. It is, when quite dry, and even warm, ready for exposure under a transparent positive. Mastery over correct exposure can only be gained by practice; for although a practised eye can detect the change in colour going forward, this cannot be much relied on. A similar judgment to that required in timing a negative must be used. About four or five minutes in the afternoon of a dull day were given, and proved just right. Under-exposure will produce a black, heavy picture; whilst slight over-exposure may be corrected, and made to yield a fine print by patient and careful development.

After exposure it is taken back to the dark room for development. The dark room should have a well-ventilated atmosphere, and have no draughts or currents of air. The dryness or hygroscopic condition of the atmosphere is of vital importance. If the air be exceedingly moist, or if currents of air holding moisture sweep through it, it becomes almost impossible to avoid patchy development; whilst if the air be absolutely dry, it is difficult to get the powder to adhere so as to develop at all. Familiarity with the conditions to be gained by practice is the only safe guide here. The plate is removed from the pressure-frames, and again thoroughly dried by heat. It is best to begin the development with the film quite dry, as a better estimate can be formed then of the exposure and the care required in development. The development is effected by the application to the film of the powder which is to form the image. For ordinary purposes it consists of ivory black and indian ink very finely powdered. The colours should be purchased of the artists' colourman as finely ground as possible, and then well ground together again in such proportions as may give the desired tint. Indian red may be used alone to give the tone of red chalk, or black alone to give the cold black of engravings; or sepia, or indeed any tint which may be desired. It is applied to the film gently with a large camel's hair brush. At this stage of the process very much rests under the control of the manipulator. Almost any depth in any part may be obtained by patient and continued application, so that the manipulator with artistic taste may materially modify the light and shade of the picture at will; whilst the careful, but mechanical, printer will produce an exact transcript of the negative. It must be borne in mind that depth is obtained by patient re-application rather than by any attempt to cause much powder to adhere at once. If the plate appear to have been over-exposed, so that the powder seems indisposed to adhere, there is a temptation to breathe upon the plate. This is a dangerous proceeding, and may cause the next application of powder to adhere in a patch. When our

friend's plates were too dry, he simply walked to a damper corner of the room, further from the Bunsen's burner, and moved the plate about in the air. The hygroscopic film quickly absorbed a little moisture, and the powder adhered satisfactorily. As each stage of the result is visible, it is not difficult to judge when the development is complete, or when a shadow requires a little deepening, or even, if desirable, light and shade introduced into a background which may be quite plain in the negative. Vignetting is also easily effected. When the image is complete, the next step is fixing it. As the nature of the fixing agent must depend to some extent on the colloid body employed in the sensitive syrup, we will say a few words on that subject before referring to fixing further.

In the first process of this kind, that of Garnier and Salmon, the syrup consisted of albumen and sugar and bichromate in water, and the images were fixed by immersion in a solution of sulphurous acid in water. M. Joubert used albumen, honey, bichromate of ammonia, and water, and his images were fixed by pouring on the film alcohol to each ounce of which three or four drops of strong nitric acid were added. In modern practice, the use of albumen has been generally abandoned, and the syrup is generally formed of gum-arabic and honey in water, or dextrine and glucose in water. Here is a formula for the latter:—

Water	1 ounce
Dextrine	24 grains
Grape sugar	24 "
Bichromate of potash	24 "

Here is another formula with gum:—

Water	6 ounces
Honey	1 drachm
Glucose	$\frac{1}{2}$ ounce
Gum-arabic...	$\frac{1}{4}$ "
Saturated solution of bichrom. ammou...	$1\frac{1}{4}$ "

Where albumen formed an important element in the syrup, alcohol and nitric acid, coagulating that substance, formed valuable fixing agents, whilst plenty of washing in water removed the unchanged chrome salt. Where, however, gum or dextrine are the chief binding elements, the same fixing agents are clearly of less value; nevertheless, they continue to be used. Some operators now, however, dispense with nitric acid, using, to an ounce of alcohol and water in equal parts, about half a dozen drops of sulphuric acid, which, being a good solvent of bichromate, rapidly aids in removing all the unchanged chrome salt. This is poured gently on the film, as at this stage it is tender, and is easily injured. Some use strong alcohol alone, and in subsequent washing add sulphuric acid to the water. After pouring off the fixing solution, the plate is very gently placed in a dish of water, which must be changed gently three or four times. The image is then dried by gentle heat. Care must be taken to keep white light from the image until all the bichromate is removed by washing.

If all the operations have been skillfully and carefully conducted, a fine picture, exceedingly delicate, yet with much vigour, is obtained, having a perfectly matt surface. Perhaps there is no form of photographic print which is so readily amenable to retouching, and is so much improved by very little work. The retouching consists as much in removal as addition. A few touches with an eraser, in making more pronounced an important light, or giving tenderness to a heavy shadow, are marvellous in effect. We commend our readers strongly to try the process, and let us know of their success.

GELATINE EMULSION FILMS SPLITTING.

We do not think there is any good reason to fear the general destruction of gelatine negatives if produced and preserved with anything like adequate care. But every suggestion is worth consideration. Mr. Foxlee, in *Autotype Notes*, suggests a very careful washing to remove fixing

salts, alum, &c.; and, further, to ensure the absence of moisture before the films are varnished, he recommends immersing the plates in strong alcohol to displace water. "It is," he says, "a good plan, when the plate has apparently been thoroughly dried, to again immerse it in spirit just before applying the varnish. After the plate has drained for a few minutes, it will prove to be quite dry by the time it is warm enough to receive the varnish."

"By taking these precautions, we shall secure a film that contains no salts that can crystallize out, and thus split it up, neither moisture which might cause it to swell. All that now remains is to protect this film from the future action of damp. For this purpose a suitable varnish must be employed, otherwise all the care hitherto bestowed on the plate will be rendered abortive. Any varnish that is of a porous or brittle character, such as those that may be rubbed up for retouching upon, or such as are soft enough to be worked upon without preparation, should be avoided, as they are apt to allow moisture to permeate them. The kind of varnish that should be used is one that possesses the opposite characteristics to those I have just alluded to. It must be hard and impenetrable by moisture, yet withal, to a certain degree, elastic, so as to permit of any little expansion or contraction of the gelatine should any occur."

FRENCH CORRESPONDENCE.

STARCH EMULSIONS—ARTIFICIAL LIGHT IN PHOTOGRAPHY—METHOD OF BLANCHING AND RESTORING PHOTOGRAPHS THAT HAVE TURNED YELLOW WITH AGE.

Emulsions of Starch more Rapid than those of Gelatine.—I have received from Barcelona a paper entitled "Instantaneous Photography," by Messrs. J. Ferrars and J. Pauli, treating more especially of emulsions of gelatino-bromide of silver. On this particular branch of the subject the authors of the work in question only reproduce what has already been published in other places; but when they describe their experiments with an emulsion of potato starch they enter on entirely new ground; with this novel preparation they seem to have attained a rapidity exceeding anything yet experienced with gelatino-bromide. So far as my imperfect knowledge of Spanish (in which language the paper is written) enables me to understand, the process adopted by Messrs. Ferrars and Pauli is as follows:—

Potato starch	4 grammes
Water	20 cub. centim.

The starch is placed in a mortar with a few drops of water, and well triturated and beaten up until it assumes the form of a thick paste, with which the 20 c.c. of water are then thoroughly mixed. The object of the trituration is to crush the starch grains, and thus to enable the water to be completely incorporated with them, the result being a more homogeneous or smoother mixture. In another vessel, capable of standing heat, the following solution is prepared:—

Water	80 cub. centim.
Potassium bromide	1.12 grammes

This solution is raised to boiling point, and the first, or starchy, liquid is gradually dropped into it, keeping it, at the same time, vigorously stirred. As they swell, the grains of starch will be completely impregnated with the potassium bromide, and this is a most important condition in securing a good emulsion. Still keeping the mixture hot, the following solution is added drop by drop:—

Distilled water	20 cub. centim.
Silver nitrate	1.62 grammes

In order that the double decomposition may now be effected, shake the mixture energetically, and without cessation, until the operation appears to be completed, which will probably be at the end of eight or ten minutes. Next pour the emulsion on a glass plate, placed in a horizontal position, and so soon as it has set sufficiently, wash

it with pure water. Redissolving the paste, filtering, coating the plates, and drying are carried out as in the ordinary gelatino-bromide process. From the higher permeability of colloidal substances—such as starch, arrowroot, sago, &c.—the authors draw a conclusion highly favourable to the superior rapidity of emulsions formed of these substances. There is also, as they observe, a marked economy in the employment of starch emulsions, and to render them firmer and more capable of development they suggest a mixed emulsion of gelatine and starch. This new direction which has been laid open to the study and improvement of emulsions appears to me to be sufficiently important to be re-recorded; it certainly will be a great advance if we can succeed in increasing the rapidity of emulsions, and at the same time in decreasing their net cost.

Photography by Artificial Light.—It can scarcely be necessary to describe to the readers of the PHOTOGRAPHIC NEWS M. Vander Weyde's process of illuminating by the electric light. This inventor is better known in England than he is in France, and he carries out himself in London his processes, for which he has taken out patents, and of which your journal has already given full descriptions. It has been stated in your columns that M. Liebert has acquired the patent rights in France of the Vander Weyde system, and your readers have also learned that in order to establish those rights he has recently commenced against M. Pierre Petit an action, which is still pending (see PHOTOGRAPHIC NEWS for 27th June, page 302). Being anxious to observe for myself the working of this method of illumination, of which I am free to confess I had but an imperfect idea, M. Liebert courteously permitted me to inspect all the arrangements he has made for carrying it out, and I left his studio fully convinced of the importance of being able to apply artificial light to photographic work. I say specially, *artificial light*, to make my meaning as general as possible, without wishing in any way to undervalue the system of double reflection invented by M. Vander Weyde for effecting conveniently a dispersion of the rays from the electric lamp. When I was some time ago consulted as to the propriety of introducing this system of illumination, I expressed a belief that however great might be the advantage of artificial light under certain circumstances, I could not conceive it to be an essential requirement in a country where there is generally an abundance of solar illumination. At the time I had in my mind the south of France, Italy, and Spain. But now that I have had the opportunity of making myself personally acquainted with the subject, I feel that my former opinions must be to a certain extent modified. The employment of artificial light where the necessary expenses are sanctioned by a business on a sufficiently large and prosperous scale will, as I now believe, be one of the first conditions of important industrial success. In principle I have always been desirous that photography should be able to transform itself from a personal art, which it is at present, to a really industrial art. When it is no longer subject to a host of difficulties, and at the mercy of every passing whim; above all, when it is capable of being worked without reference to the time of day, or to the more or less feeble intensity of the solar rays, then it will assume that position of a grand art of which we are continually dreaming. The use of artificial light is a decided step in this direction, and what I more especially admire in the system of reflection adopted by M. Vander Weyde is the power not only of illuminating the object to be copied with greater softness, but also of graduating the light and modifying the arrangement of the shadows in a more rapid manner than by natural illumination. In talking the subject over with M. Liebert, I suggested that in order to avoid the somewhat dazzling glare produced by the whiteness of the large reflector, the white paper which covers it should be replaced by one of either a blue or a violet colour. I believe that by adopting this suggestion a softer light, and one which would be better supported by the sitter, would be maintained without losing rapidity. But this is

only a question of detail, which does not affect in the slightest degree the great principle of employing an artificial source of light. As has been already said, upon that principle depends the most effective means of organising a photographic atelier; and how great will be the superiority of one who is thus able to work in all weathers at any hours, and always in a fine full light, over those who have only the sun at their disposal—a sun so often veiled! For him there will be no occasion to fear either over- or under-exposure; the operator will have almost a mathematical knowledge of his light, and will be able to work with absolute certainty. And then if, instead of still having recourse to the ancient wet collodion, he will freely enter on the new path of progress, and take up dry gelatino-bromide plates, the average time of the exposure need not exceed one or two seconds. What an economy of time this will be! No more agonized sufferers, fixed in the rack, and tortured by the magic spell, "Don't move!" No more head-rests! No more restrained breathing, followed by the sigh of satisfaction, and the exclamation, "Thank Goodness, that's over!" And then there is the vexatious discovery that, after all, the gentleman or the lady *had* moved; and the trouble and annoyance when children have to be taken. All this will be changed under the new regime. Now, when we look around and see whether these improved appliances and processes have become common, we find they are not in more general use than Woodburytype or phototypic. And to the question why this should be so? I reply, it is because no popularization will ever be possible. What will happen will be the creation of a number of huge photographic establishments, furnished with all the means and appliances which characterise the industrial progress of this branch of applied science. The smaller photographic establishments will gradually die out. Photography itself, as an industrial art, will become a branch of printing, as engraving and lithography have already become. Has it not already made a step in this direction by giving rise to the creation of photo-zincographic workshops, which are nothing more than auxiliaries to typographic printing? And that, auxiliaries scarcely known, for the larger number of photo-typographic plates that we meet with in illustrated works bear no trace of their origin or of the method by which they have been executed. When once plates produced by phototypic are printed in the text, and simultaneously with the type, the same thing will happen: the great printing industry will entirely absorb photography to its own profit, and when that day arrives, our art will have arrived at the apogee of its valuable work. For these reasons I am led to rank the use of artificial light in photographic studios among the most important industrial improvements in photography—a light, that is to say, such as that used by M. Liebert for portrait taking, or as that applied by Messrs. Goupil and Co. and M. Dugardin to other branches of photography. Artificial light generally is still in a state of change; but for photographic purposes it promises to have an important application.

Method of Restoring Old Photographic Prints.—Pending the discovery of a means of introducing into albumen some substance which will prevent it from turning yellow (see PHOTOGRAPHIC NEWS for 1st August, page 361), it may be useful to know that a process exists by which this yellowness can be got rid of when it has made its appearance. I have tried the following method with satisfactory results:—Remove the print from its mount, and immerse it in a bath consisting of—

Filtered water	1,000 gr.
Saturated solution of mercury bichlorid in hydrochloric acid	20 drops

Leave the print in this bath until the required tone be restored, and wash freely. If the picture should fade, dip it in a bath of liquid ammonia diluted with water.

LEON VIDAL.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER II.

ON THE WING--NEW ACQUAINTANCES--THE AMATEUR'S FIXING BATH.

MOST young men have a desire to go forth into the world and see fresh scenes, to cross oceans and become miniature Cooks and Columbus, to climb mountains and sleep out at nights by the camp fire, and otherwise imitate the wanderers of the desert as if they were to the manner born. This Bohemian feeling was very strong upon me during my stay with Ballarat. When our sitters gasped for breath and wiped the streams of perspiration from their brows, when the sky was without a cloud, when the bath had to get sundry applications of ice, and the "new developer" had to give place to Bass's bitter, then did that restless feeling take possession of me—then did I want to go forth and wander over plains, climb rocks, stand on mountain tops, and, in short, breathe a more extensive atmosphere than the six-foot square of Ballarat's dark room. I do not know what might have been the upshot of these restless fits, if fortune had not seen fit to favour me by granting what I so devoutly wished for.

One bright morning a traveller dropped into Ballarat's, and in the course of conversation he exclaimed, "There's a nice chance for a couple of young fellows to see a bit about them just now; the noble Marquess B—and a few other nobs are about to do Iceland, and they want a first-class man and two assistants to go along and take views!"

I nearly dropped the negative I was varnishing in the hurry with which I turned round and exclaimed, "Assistants not engaged?"

"No," answered the traveller; "but the head man is, though. I know him well—a strange fellow that will not speak three words sometimes in a day—but a good operator for field work, and a straightforward man for all that. Why do you ask? Should you like to go?"

Should I like to go! Great heavens! I thought the man a lunatic to waste words in asking such a question. The blood was coursing through my veins with electric speed as, trembling with excitement, I rose and answered with the greatest unctiousness, "Shouldn't I?"

As I spoke the words my eye caught Ballarat's. There was such a pained look on his great face that my heart smote me, and I was on the point of qualifying my exclamation, when the traveller, producing his note-book, said, "Make your preparations at once; you shall have the job. Give me your address; I shall write to Gilbey at once, and you will hear from him the day after to-morrow, stating the terms and where you are to meet him."

It is impossible to describe my state of mind during the next two days: at one moment I was in the clouds with a glorious happiness in my heart, such as we experience only once or twice in life; and the next I was a prey to despair, as I thought that perhaps some more favoured mortal might have been before me, and secured the coveted situation. Ballarat, during those two days, was gruff and surly, plainly giving me to understand that he did not approve of the change. However, he behaved very friendly when I did get the situation (yes, I did get it!—that day is marked with a white stone, I can tell you!), and gave me a lot of useful advice about my baggage, and, what I thought more of at the time, an extra sovereign to help me on the way. He shook hands heartily, and hurried away to look after his business and his new developer, while I rushed off to the station. I recollect how nearly I lost the train. As I hurried along I passed a book-stall, and the tail of my eye (if eyes have such appendages) caught on the title page of a book; on that page was the magic word "Iceland." It would have been a sin not to have bought that book, and I would have been more than

mortal if I could have resisted the temptation of informing the shopman that I was on my way to that remote and mysterious island; this I informed him in an off-hand manner, as if such a journey was an everyday occurrence. The train was leaving the platform as I rushed up to it. "Hold him back!" "Let him alone!" shouted a number of people. Then I was pushed behind, and hauled in front, and finally got landed all right in a third-class compartment. I had no relations to see me off, and my friends were all at business, so that I felt pleased that my departure was not altogether unnoticed.

I had orders to join Mr. Gilbey at Ardrossan, a small seaport on the Firth of Clyde. I had to go by Glasgow, and in due course arrived at that busy city. I was rather startled just now when, upon looking over the notes of that famous journey, I found the following entry:—"Glasgow—huge masses of grimy houses, emitting volumes of smoke that will not disperse, and smells that assail the nostrils and sicken unto death; the inhabitants white-faced, wild in their talk, bewildered in their manners, their sole aim being to make enough of money to pay their passage to a purer atmosphere. Am thankful that my passage is paid."

It is evident that Glasgow did not awaken my admiration.

A hasty meal, and I was on the river. There were no saloon boats in those days—no princely *Jonas*. A penny paddle steamer of the earliest pattern was the means of transport then; and the passengers were packed with the tea and sugar, the tar and treacle, the whiskey and what-nots that comprised the miscellaneous cargo.

While I sat on a box of soap, alternately admiring the scenery, and listening to the awful sounds of a solemn piper who enlivened us with a few of his native pibrochs, my eyes lighted upon a young man intently devouring the pages of a book. Now, there was nothing to startle me in that—nor was there anything particular in the young man's personal appearance, except that he had large eyes, long hair, and fur on his coat collar and half way up his arms; but, nevertheless, I was startled—startled to see that the book he was so intent upon was a facsimile of the one I had bought.

Heavens! Here was a coincidence! A young man studying the history of Iceland! Surely I had not dropped my copy? No, it was safe in my pocket. My excitement was great—so great that I at once crossed the deck and entered into conversation with him.

In an instant the book disappeared in his pocket, and with remarkable volubility he commenced to talk—talk—talk. There was never such a fellow to talk. Although I was bursting to put some questions to him, it was a good half-hour before I had the ghost of a chance. At length he stopped to lick his lips, and I thrust in the question, "You have travelled far?"

"Should think so! When I was——"

"Know anything about Iceland?"

"Iceland?" he repeated, and giving me a wink that said plainly, 'You could not have come to a better party for information,' he cleared his throat, and started off. "A thousand years ago, the remote island of Iceland was colonized by successive swarms of Northmen, who fled thither from the Scandinavian mainland, in order to escape from the tyranny of their kings. They took with them cattle and ——"

He stopped short in his declamation here, and looked at me in surprise, for I had quietly produced my book of Iceland, and was calmly following the lines, as he spoke them, with my finger.

A hearty laugh, a hearty shake of our hands, and Tom Howie and I commenced a friendship that only ended with his death.

It is needless to say that he was the other assistant, and that, like myself, he was bound for the rendezvous at Ardrossan. I may here state that Tom was a thoroughly

kind-hearted fellow, a steady workman, and a clean manipulator: rather fond of fun, and the best hand at drawing the long bow that ever it was my fortune to meet with. This long bow practice of his was a sort of social infirmity or genial weakness; it never offended or hurt—it seemed, as it were, to spread a broad grin all round; it opened the eyes with wonder and chained the speech with delight; it pricked up the imagination, set it on a sun-beam, and tickled its ribs until it roared again.

It was on board of ship, and during the long stormy days we experienced in Iceland, that Tom's powers got thoroughly tried. As an instance, I may here introduce our third evening at sea. We had left the Orkneys in the afternoon, and were heading for the North Sea under easy sail. We were seated near the capstan among a lot of spars and ropes, enjoying a smoke (the Pentland Firth had cured us of our sea sickness), when the conversation turned upon the fixing of negatives.

"Cyanide for ever—nothing like it!" shouted Tom.

"Hypo!" was Gilbey's laconic defiance.

"How! Prefer that vile contaminating sloth to the clean working cyanide?" cried Tom.

"Yes," mumbled Gilbey, exhibiting his left hand, on which you could only count three fingers. "My forefinger was a clean piece of work, was it not? That was through cyanide. A friend of mine is buried at St. Leonards—the doctors said he had inhaled some poison—he fixed with cyanide! Very clean work! Hypo is the thing. Leaves the half-tones, gives a better printing colour to the film, and is harmless to the operator."

This was an awfully long speech for Gilbey to make, and Tom was rather struck with his logic. At last he cried, "But look at the washing!"

"Are we lazy?" asked Gilbey, elevating his eyes.

"No, by no manner of means," replied Tom; "but it is only good rules that work both ways, and I can prove to you that this one is at fault. Just the other day, when I was toiling away at old Carey's, who should drop in but an amateur—a mighty great swell, I can tell you—has dogs, and horses, and estates, and all manner of things; and after a few cursory remarks upon one thing or other, he says, 'Aha! you are going to photograph that lady. May I come in the dark room with you?' 'Certainly, my dear sir, with pleasure.' So accordingly everything went all right until I came to the finishing of the negative. 'What do you fix with—eh?' asked my friend. 'Cyanide of potassium,' I answered, as I dashed the liquid over the plate. He made some remarks at the time, but being engrossed with my negative, I did not note what they were about. Just as he was leaving he said, 'What strength do you use the cyanide?' 'Oh! about an ounce to a pint.' 'Oh! thank you,' quoth he. 'Good afternoon.' I thought no more about the young swell until next evening, when, just about the time we went to tone, he suddenly appeared in the doorway. His face was pale, his manner excited, and his voice trembled with emotion as he asked to be allowed to see us tone and fix our prints. With pleasure once more. I took him under my sheltering wing, and gave him as nice a lesson in washing and toning as ever anyone need wish for. But, to my astonishment, his excitement and emotion only increased. 'Now,' I cried, 'we come to the fixing.' 'You should have seen him start and change colour at that.' 'To-night we make a new fixing bath,' I continued, 'and you shall see how it is done.' 'Behold!' I cried, as I dived into the hypo barrel, and brought forth about half-a-pound; 'this is how we do it.'

"Good Gad!" shrieked the amateur, "you don't mean to say you use all that?"

"I do. Why?"

"Why, be—because I did not use the sixth part of that last night, and in less than two minutes all my nice—nice prints were out of sight." And the poor young man wept.

"Out of sight in less than two minutes?" I cried "Impossible! What on earth did you fix them with?"

"Cy—cyanide—o—of potassium!" he added; "the same that you used in the dark room."

"Now, Mr. Gilbey," quoth Tom, "you see there is something rotten somewhere."

(To be continued.)

CORNWALL ROYAL POLYTECHNIC EXHIBITION.

JUDGES' REPORT ON PHOTOGRAPHY.

The judges of photography reported that although there is a slight falling off in the number of exhibits compared with last year's exhibition, they are exceedingly pleased with the high technical excellence displayed, especially in the new dry plate process, which seems to have come to the front during the past two or three years. The exhibits by the gelatine dry-plate process are most remarkable. Under the name of platinotype, a new printing process has been introduced, combining permanency with simplicity. The judges have great pleasure in congratulating the Society on the quality of the exhibits generally, if not on the number. Section 1 (Professional), for the best landscape in the exhibition, has been awarded to Mr. Payne Jennings a first silver medal, for English and Irish scenery, which, while possessing force and brilliancy, are extremely soft and delicate, and are of high artistic excellence. Messrs. Wratten and Wainwright are awarded a first silver medal for their instantaneous pictures, No. 625, of the University Boat Race, 1879, taken on gelatine emulsion plates. They are truly miraculous productions, and in two of the prints especially the river teems with life, and every wave is portrayed, and the judges consider them the most perfect examples of instantaneous photography ever exhibited. Mr. Willis, jun., exhibits some very fine examples of portraits and views printed by his new platinotype process, which are permanent. Platinum is here used in place of the fugitive silver compounds. A second silver medal has been awarded to the process. For a frame of interiors a second silver medal is awarded to Mr. R. C. Lenthall, of Reigate, taken by the gelatine process. They are very excellent productions. In interiors it is generally noticed that violent contrasts predominate, which is not the case here.

In the Portraiture Department the exhibits are very few, especially in large work. A first bronze medal has been awarded to Mr. W. Gillard for a portrait study taken direct, which possesses some very excellent qualities. Messrs. Hills and Saunders, of London, send a frame of particularly fine examples of cabinet size, studies of children. The judges consider them the finest examples of portraiture in the exhibition. As a rule, white draperies come out a meaningless white mass; but by the peculiarities of the gelatine process this defect is entirely overcome. A first bronze medal has been awarded to this exhibit. Mr. E. Greaves has also been awarded a first bronze medal for his studies from life. A second bronze medal is given to Messrs. Russel and Sons for a very fine group by the gelatine process. For an enlarged group, printed in carbon, of the members of the South London Photographic Society, by Mr. H. G. Cocking, a second bronze medal has been awarded. The judges call special attention to some fine examples of portraiture taken at night by the Luxograph process, showing that a new sphere has been opened to this art. The specimens sent of a fancy dress ball are nearly, if not quite, equal to portraits taken by daylight. The judges regret that owing to some of the same pictures having been sent by two exhibitors they were unable to make an award. Mr. Baker, of Birmingham, sends some examples of cabinet portraiture which are very clear. Mr. H. G. Cocking also contributes three figure studies, but the judges do not think them quite up to his standard. Mr. Hollyer has some charming little artistic sketches of rustic life. Mr. J. Milman Brown is again a contributor and the judges are pleased to see an improvement in his work

a country road being the best. Mr. George Nesbitt exhibits some single figures studies which are very fine.

In Section 2 (Amateurs) Mr. W. J. A. Grant has sent some exceedingly fine photographs of the Arctic regions taken during the expedition of 1878, for which he had been given a second silver medal. The judges had taken into consideration the extreme difficulty in working of the Society's exhibition. Mr. George F. Powell's stereoscopic slides of ferns and flowers show merit. It is a pleasure to see Mr. Charles A. Ferneley helping the Society by exhibiting some delicately manipulated rustic studies, and the judges note that he has taken the hint given last year, and has added to the beauty of his productions by printing in skies. Mr. H. M. White's series of photo-ceramics are numerous and interesting.

Section 3. Photographic Appliances.—The exhibits of Mr. George Hare show wonderful ingenuity and excellent finish, and to the dry plate changing-box has been awarded a first bronze medal. Messrs. Avery and Co. send examples of material suitable for photographic backgrounds, which are highly commended. The duplex lecture lantern of Mr. H. Keevil shows some useful novelties. To it the judges have awarded a first bronze medal. Malden's triple lantern, by Mr. J. Middleton, of London, is a noble instrument, and shows several original points. It is in every way a most perfect instrument, and well deserves the second silver medal which it has gained.

Correspondence.

WASHING PRINTS.

SIR,—I send you a plan of a most efficient method of washing prints, which I have had in use for some years; it is thoroughly efficient, and, what is to the purpose, self-acting. Fig. 1, A, is an American pail, pierced with holes,

Fig. 1.

Fig. 2.

b b, about 4 inches from top. *c c* is a small white-metal gas piping, which is curved at the bottom of fig. 2, and is pierced with numerous small holes, which increase in size as they approach the end of the pipe at *c*. A small funnel placed in *c*, and a wooden cover, complete the arrangement. The prints being placed in the pail, the latter is placed under a tap, when the force of the water will be at once manifest by spurting to some distance above the top. When the water arrives at the holes *b*, the action of the pail resembles a running stream, for all the water enters at the bottom and conveys with it all impurities at the top; whereas in the ordinary method of pouring water on the top, the lower layers of water remain undistilled.

My method shortens the time for washing considerably, and I am satisfied that after one or two preliminary washings, four hours will render a large batch of prints perfectly safe.

The pail should be painted some days previously with some hard paint.—I am, yours obediently,

SOLOMON SMUDGE.

GELATINE FILMS HONEYCOMBING.

SIR,—I hope there are not many who are experienced in honeycombed films, a calamity that "B. S." has been overtaken by. You suggest "frilling"; but that is placed somewhat out of court by the peculiarity appearing as soon as they "begin to set."

I, for one, have never had such an unpleasant experience, although I was shown a short time back a batch of plates which were very seriously affected in that way, and I regret I did not examine them more closely. It appeared to me evident that the washed emulsion from which they had been coated had been so charged with a preservative or substance for perhaps producing insolubility as to cause on drying the same sort of cracked film that one sees occasionally in ancient pictures. It would have been difficult to have told, however, the cause without knowing details of the entire process by which the plates had been produced.

The same brittleness and cracking of the gelatine that might be supposed to follow a treatment of a large dose of acid previous to washing, or a want of adhesiveness which may follow an addition of glycerine to the finished emulsion, may not in any way resemble the honeycombing spoken of by "B. S.," especially if he has not been "doctoring" his gelatino-bromide by any such addition; and probably the mottling due to an excessive dose of alcohol might be easily mistaken for the graver fault, all of which is extremely difficult to surmise even, leave alone saying anything definite about it without seeing a plate, unless some one, also, may have been equally unfortunate as himself, and traced the cause. If "B. S." would send me a plate, or part of one, to the enclosed address, if I could divine the cause I should be happy to communicate it to him, and, in addition, he would satisfy a curiosity on my part to see the fault alluded to, as I know of no one personally who has experienced the same.—Yours faithfully,

CHARLES BENNETT.

South Lancing, Worthing, Sussex, September 10.

Proceedings of Societies.

BOLTON PHOTOGRAPHIC SOCIETY.

THE amateur photographers of this town have long felt the want of an association in which their particular "hobby" might be more freely discussed, and occupy a more prominent place than it can do under any existing association. On Thursday evening, Sept. 5th, an influential meeting of the local amateurs took place in the Reform Club, when, after a most interesting discussion, it was decided to form an association to be called the Bolton Photographic Society,—the meetings to be held the first Thursday in each month at the Bath's Assembly Rooms. The following officers were appointed:

President—Mr. Parkinson, Bolton Grammar School.

Secretary—Mr. John H. Galloway, Bolton Brass Works.

Treasurer—Mr. Wm. Banks, Optician, Corporation Street.

Council—Messrs. Shipperbottom, Rideont, Wigglesworth, Tonge, Dalton, and Grundy.

The Association commences with a membership of about thirty, and there is every promise of a most successful issue.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board of Management of this Association held their usual monthly meeting on Wednesday, 3rd inst., at 160A, Aldersgate Street.

The minutes of the previous meeting were read and confirmed.

Mr. STRIVENS was then elected an ordinary member of the

Association, having been proposed by Mr. J. D. Fage, and seconded by Mr. J. D. O'Connor.

After other business of the Association was completed, the meeting adjourned until October 1st, at 8 p.m.

Talk in the Studio.

"SARONY IS DEAD.—No great general, or minister, or traveller, or diplomatist was Sarony; only a photographer. Yet Sarony was a genius of his time, and manipulated the secrets of his 'art' with a skill sufficient to land him at the head of his profession. His patrons were numerous enough to place him in command of capital, and with that essential to success he worked out his experiments. He lived to distribute the fruits of many triumphant theories, and to graft upon 'ideas' of his own the discoveries of his brethren in Broadway and in Paris. Scarborough, remarkable for many good things, became celebrated for Sarony's photographs, of which it may be said that they neutralised the popular defects incidental to our unemotional atmosphere."—*The Whitehall Review*.

THE OLDEST SCIENTIFIC LECTURER.—M. Chevreul, now in his ninety-third year, began his usual course of lectures on organic chemistry at the Museum of Natural History, Paris, on June 10th.

RETOUCHING VARNISH.—A good retouching varnish is a boon to all retouchers, and those who are unfortunate enough to be plagued by too thin films will gladly hail a formula which promises this desideratum. In his recent work on retouching, M. Janssen, the *Photo. Correspondenz* says, recommends the following varnish:

Alcohol (sp. gr. 0.830)	60 parts
Sandarac	10 "
Camphor	2 "
Venetian turpentine	4 "
Oil of lavender	3 "

This varnish may also be used for paper pictures. The retoucher should not set to work as soon as the negative has been varnished, as the film will not then be hard enough to bear the touch of a lead pencil. The varnished film is in the best condition for retouching when a day old.—*Scientific American*.

GLOSS FOR PHOTOS.—The same gentleman also gives a formula (said to be used by Salomon, of Paris) for a cerate for giving a high gloss to albumenized pictures. The components are:

White wax	800 grammes
Elemi resin	10 "
Oil of lavender	300 "
Benzoin resin	200 "
Oil of spikenard	15 "

THE ALLEGED DISCOVERY OF A NEW SOURCE OF LIGHT AND HEAT.—The alleged discoverer of the new source of light and heat to which we recently referred, writes to the English press as follows:—"Monsieur,—Je viens de lire dans votre estimable journal un article qui traite mon invention de canard. Cela ne me surprend pas. Monsieur, votre grand-père il y a cent ans aurait pu être traité de fou s'il avait dit que l'on pourrait bientôt courir quarante voitures à la fois, et sans chevaux, ce que font nos chemin de fer aujourd'hui. Ne vous en déplaîse, Monsieur, mon invention n'est pas un canard, et je prétends qu'aux moyens de mon invention on chauffera un bateau à vapeur aussi bien qu'une tasse de café. Veuillez, Monsieur, me faire l'honneur d'une visite, et vous serez convaincus de la vérité.—Recevez, Monsieur, mes salutations empressées, C. BOMBONNEL, à Dijon.

To Correspondents.

SOUTH DEVON.—We do not know with certainty. Try any of the photographic dealers. Or cover a white one with crimson paper, or varnish with a ruby varnish.

A. B. C.—As a rule, a good negative which has been developed simply, and not intensified or redeveloped, is best for the purpose of the retoucher, and gives most scope for skill in retouching, as lights can be put in and detail brought out with more force by the retoucher's pencil.

W. W. FREE.—An alkaline developer will best bring up your underexposed dry plates by the coffee process. Or you may bring out detail by using a plain pyro developer, and obtain density then with pyro acid and silver. 2. Much depends on the position of the studio; if it stand in an open position accessible to sunshine, corrugated glass will serve for the roof, but not for the north side-light.

A. A. G.—With the camera you propose to get you will be able to enlarge to 12 by 10 inches with your small Voightlander. In calculating for enlargements it is necessary to know the equivalent focus of the lens, which is not the same as the back focus. If your lens give an image the same size when the camera is extended ten inches, the equivalent focus of the lens is about five inches. The amount of extension of camera is not difficult to calculate. To produce a copy the same size requires an extension of double the equivalent focus; for twice the size, an extension of three times the equivalent focus; for thrice the size, four times the equivalent focus. So with any number of times of enlargement, the extension must be once more than that number of times the equivalent focus. In some of our back YEAR-BOOKS you will find tables giving all the details for many sizes.

W. GERMANUS SHAW.—The letter was duly addressed and posted.

ROBIN.—The reason of the film splitting up when transferred to the surface of a metal arises, we presume, from the collodion being contractile, and when it is transferred to the metal surface it is not in a state of perfect and adhesive contact with the metal, hence it splits when it dries, and contracts. Possibly a less tough and contractile collodion would give better results. We do not see how a collodion image on metal is to be made useful for engraving.

J. G.—Shellac dissolved in methylated spirit makes a very good varnish. Castor oil, at the rate of four or five drops to the ounce, makes it more tough and elastic, and less friable. But we recommend the purchase of a good negative varnish. Amateur varnish making is risky and troublesome.

J. L.—For most commercial samples of albumenized paper a forty-grain silver bath answers well.

NEMO.—Place a folded sheet of blotting-paper which has been immersed in a strong solution of carbonate of soda, and dried, at the back of the sensitive paper in the pressure-frame. This will prevent discolouration during long printing.

STAINER.—A relief like that used in the Woodbury printing process would give by pressure such printing as you desire, scarcely to be seen by reflected light, but transparent by transmitted light.

CHROMATOPHILUS.—A carbon print transferred to plain paper would give the result you desire, a glossy image on a matt surface, the lights being quite a dead white.

PLAIN ENGLISH.—The formation of a Company in this country to manufacture a style of goods hitherto manufactured on the Continent, and imported into this country, may without any impropriety assume the name of an "English" company, even if it engage foreign workmen to make sure of the style not being lost or modified. Hence a letter commenting unfavourably on such points is not suitable to our columns.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

CAN THE CAMERA BE EMPLOYED IN CONNECTION WITH MANCE'S HELIOGRAPH?—PHOTOGRAPHY IN COLOURS.

Can the Camera be Employed in connection with Mance's Helio-graph?—Sunshine signals are again to the fore, and the heliograph is to play a more important part than ever in warfare. The Shutargardan Pass, which has already been occupied by British troops in a second advance towards Cabul, is distant from the Afghan capital but fifty-five miles, and General Roberts will seek, therefore, to establish a light-signalling station on the Pass in order to be able to communicate with his base when he has reached Cabul. The Shutargardan stands above eleven thousand feet, so that there will be no difficulty in flashing light-signals thence into the plain. It is a pity that Mr. Mance, to whom is due the credit of constructing the heliograph, did not choose some other name for his invention when he submitted it to Government in 1869. Heliographs and helio-gravure were words in common use by photographic investigators thirty years previously, for we had heliographs before we had Daguerreotypes. Nicéphore Niepce, in his early experiments, employed the words, and we saw in the last Paris Exhibition a specimen of helio-gravure produced by that early pioneer in 1824. Again, we usually, although not always, employ the terminal "graph" to something which records, and has connection with the graphic arts. In the Mance heliograph the signals are simply seen, and not recorded. A person looking afar sees a succession of star-like flashes that sometimes last for several seconds, and sometimes appear only for a moment. They are long signals and short signals transmitted by the heliograph, and an alphabet is used which consists of these long and short signals. This alphabet is based upon the Morse system, and a well-practised signaller can spell through a message from these flashes at the rate of from ten to twelve words a minute. But it would be better still if an instrument could be employed instead of a man to receive the signals, since nothing could escape an automatic machine, while at the same time the signals would be written down, and would be referred to afterwards. In this case we should have a real heliograph, and we cannot see why such an improvement could not be effected with the aid of photography. In the Morse alphabet, as adopted in the telegraph service, a short signal and long signal are written down in the form of short lines and long lines. A short line followed by a long line mean A, just as a man seeing a short flash followed by a longer one would know that the signaller mean to indicate A. A long signal followed by three short ones signify B, a short signal by itself is E, and a long one T. Now it would be a very easy matter to convert a light shining for a brief time into a short stroke, and a light shining for a longer time into a long stroke, with the aid of a camera and a movable sensitive film. Our camera is of elongated shape, something like a telescope, and this camera is directed in such a way that when the signaller at a distant station shows a light, this light is thrown upon the focussing screen or sensitive plate in the form of a star. If the sensitive plate is moving along gradually at a certain fixed rate—we will say three inches per minute—it stands to reason that the star shining for three or four seconds will mark a line of some length upon the plate. If the star of four seconds' duration is followed by another of only one second, we shall have a short line produced on the moving plate immediately following the long mark. In other words, we should have written down upon the plate a long line and a short line, and this, according to the Morse code, would signify N. By having recourse to a camera in this fashion, you would not only enjoy the advantage of written signals that might be

read afterwards, but it would be possible to signal much faster, for the receiver, instead of requiring time to puzzle over the message as it was transmitted, need pay no attention until the complete sentence was before him. No doubt there would be certain practical difficulties to be overcome in adapting the camera to the heliograph, but applications of a like nature are practised every day by scientific men. The Mance heliograph as now used is a very simple contrivance, and as photographers are interested in all that pertains to light, they might like to know how the apparatus is worked. It consists simply of a tripod, upon which stands a mirror. This mirror is usually ten or twelve inches in diameter, and a glass of this size is capable of reflecting a ray visible to the naked eye at a distance of fifty miles, and even more in clear weather. The mirror is movable, swinging like an ordinary toilet looking-glass, but it has, moreover, a pivot at top and bottom that permits it also to be turned sideways. In this way it is possible, whenever the sun shines, to reflect a ray in any direction, unless it should happen that the sun is too far behind, when the difficulty is at once obviated by bringing into play a second mirror, which reflects the rays on to the first. But if the distance to be signalled is fifty miles off, it is necessary that the signaller should aim perfectly straight, and to do this he handles his mirror after the manner of a rifle. He gets behind it, and looks through a hole in the centre (where the quicksilver has been removed), and having sighted the station afar off, he brings up in a line with his eye and the station a small stud that slides on a sighting rod, some ten yards in front of the mirror. When this stud covers the distant station, the aim of the mirror is correct, and all the signaller has to do is to see that the reflection of his mirror shines upon the stud. So long as this is the case he may be sure his brother afar off will see the reflection too. A key to be pressed by the hand is in connection with the mirror, and throws the reflection on and off the stud, and by pressing this key for short or long intervals, short or long flashes are produced. This is the whole story of the heliograph; and now that our readers have learnt its *modus operandi*, we hope some of them will set to work and apply a camera to it in such a way that the flashes may be recorded and true light impressions produced by its means.

Photography in Colours.—Captain Abney's interesting results in connection with the production of colours in the photographic film, to which he called the attention of the Royal Society a little while ago, recalls to mind the series of coloured pictures which Madame Niepce de St. Victor exhibited a few years ago at the Photographic Society. Captain Abney, we believe, has photographed in a tolerably complete manner, the spectrum (we have not, by the way, yet seen his results), while the series of coloured pictures produced by Niepce de St. Victor were reproductions of coloured dolls, Becquerel, it may be remembered, having previously secured a picture of a parrot in colours. The Niepce de St. Victor series, which we inspected no less than seven years after they had been produced, were upon thin metal plates that bore a striking resemblance to the so-called American alba-plates of to-day. The models were dolls dressed in coloured raiment, and in the photograph these colours were distinctly portrayed. We suppose there were not less than fifty coloured pictures in the series we saw. In all probability very long exposures had been given in bright sunlight, and there is little doubt that they were produced by the violet sub-chloride of silver. The fact that none of the pictures exhibited pure whites bore out this impression. The plates were of course preserved in the dark, and only looked at in subdued light.

THE TIMES ON AUTOTYPES.

An interesting article appeared in a recent issue of the *Times*, devoted to a review of some autotype reproductions of paintings. The writer says:—

"On a former occasion at some considerable length, and more recently in various articles upon the progress of photography, we have made mention of the class of works called autotypes; but these, in the peculiar sense in which they have been rendered absolute reproductions of everything which is characteristic of the artist's hand in a drawing, or even in an oil-painting, will fairly admit of a more detailed notice than has yet been given to them. An engraving, however skilfully executed, is at best but a copy of a painter's work by some one else, and is thus deprived of that strictly personal element which is so important in every form of art; while in the case of autotypes the original may almost be said to copy itself, and the copies may certainly be said to reproduce with entire fidelity everything that is characteristic of the original. The work of the brush is, indeed, not so much copied as multiplied; and hence many painters of repute—notably Sir F. Leighton, Mr. Poynter, Mr. Elmore, Mr. George Earl, and others—are intrusting their pictures to the Autotype Company rather than to the engraver for the supply of the copies demanded by the public.

"A finished autotype is a sun-picture printed permanently in carbon or other imperishable pigment; and it is obtained in the following manner:—A sheet of paper is covered with a film of gelatine, with which the pigment and a certain proportion of bichromate of potash have been mixed, and this film is dried for use. The gelatine is naturally highly soluble in water, but the effect of the addition of bichromate of potash is to confer upon it the property of becoming insoluble as a consequence of exposure to the action of light. The result is that when, after a sufficient period of exposure under a negative, the prepared sheet is placed in a warm bath, the parts upon which light has fallen remain, while those upon which light has not fallen are readily washed away. Hence the transparent parts of the negative become the dark parts of the print and *vice versa*; while the dark parts, being dependent for their colour upon carbon, or upon some equally permanent material, and not upon the comparatively unstable metallic oxides of ordinary photography, are as imperishable as work done in printer's ink. An autotype is, therefore, calculated to be in all respects as enduring as an engraving.

"A satisfactory photographic copy of an ordinary painting is an obvious impossibility, because different periods of exposure would be required in order that the different colours of the surface might influence the sensitive film in the same degree, and hence every photograph of such a painting presents faulty lights and shadows. The reproduction of a picture by the autotype process requires the co-operation of the painter with the photographer, and is effected in the following manner:—In the first place, a negative is taken directly from the picture, and from this negative a transparency is printed, which, when it is held up to the light, gives the best result which can be obtained by direct photography in the particular instance. From this transparency, placed in a suitable position, a second and enlarged negative is made, the size of which depends somewhat upon the style of work affected by the artist. From this enlarged negative a print in pigment is taken, which may be upon almost any material at the pleasure of the artist, such as rough or smooth paper, canvas, or panel; and upon this print he works in monochrome, correcting all that is faulty in the lights and shadows, and reproducing his picture himself upon the lines of the photographic copy. In doing this he may be guided by having a duplicate of the original print, to show the extent of his alterations; and he may have fresh copies taken as often as he pleases, to show the effect which his brush work will produce when copied by the camera. When the monochrome picture is completed to his satisfaction, it serves as an original, from which a negative of any size smaller than itself can be taken in a camera, and from this negative any number of permanent autotype copies can be printed in the ordinary manner.

"There are certain differences of opinion among artists with regard to the method in which the picture in mono-

chrome should be produced. There are some who think that the best method is to work with the brush either in oil or in water-colour, and to depend for effect purely upon gradation. There are others, and some of them with special photographic knowledge, who prefer to proceed by dot and line, or by a mixture of both; and in this case to make the monochrome of at least double the dimensions—that is, of four times the area—which will be required in the print to be reproduced. The reduction in size has, of course, a condensing influence upon the handling, and brings it down so as to produce practically almost the same effect as the gradation of tint. There can be little doubt that the former of these methods is the best, if the artist will take the necessary pains; but the latter produces a tolerable result with less expenditure of labour. An excellent example of the former is afforded by the autotype reproduction of Mr. Richard Elmore's well-known painting of 'Windsor Castle at Sunrise.' The original picture was about 7ft. by 4ft., and the direct copy was about 4ft. by 2ft. 4in. This print, developed on paper and mounted on a canvas support, gave Mr. Elmore the whole of the drawing and composition of the original, and enabled him, without too great an expenditure of time, to modify the light and shade to the required extent, so as to obtain a perfect copy, itself the work of his own hands. To this end, he painted upon the print in oil colour, and was furnished with occasional copies during the process, so as to assist in guiding him to a correct appreciation of the value of his gradations of tint from a photographic point of view. The ultimate result is a finished autotype, which places before the eye the touch and expression of the artist in a manner which it would be hopeless to expect from an engraving, and which has the collateral advantage of being of much smaller cost. Every mark of brush work is displayed with fidelity, and the points where the painter has massed colour for the production of his effects are so truly rendered that it is at first sight difficult to believe in the level character of the surface. The autotype is published in two sizes, respectively about 32in. by 19in. and about 19in. by 12in., both signed by the artist as evidence of his approval. It is also published in two colours—in black and white and in sepia; and the sepia copies, if closely framed, might be mistaken for original drawings by even a very close observer. Moreover, the autotypes have the advantage of being all alike. No injury is done to the negative in the process of printing, and hence the last copies will be as good as the first. It might in some cases be desirable to limit by agreement the number of copies to be produced; but an artist whose work is popularized in this manner is at least spared the sight of those melancholy impressions from old plates worn to the bones and carelessly retouched, which give so poor a notion of the originals from which they were derived. In the autotypes of Mr. Elmore's picture there is a subtle blending of light and shade, and a perfection of pictorial effect, which must be seen to be appreciated.

"An illustration of the alternative manner of working is afforded by the reproductions of Messrs. Hopkiss and Havell's picture of Her Majesty's buckhounds, some of the copies of which have been coloured by hand to imitate the original. In these, of course, the original method of producing the monochrome is completely disguised; but in the uncoloured copies, as in those of all pictures produced in a similar manner, there is less appearance of personality than when the more laborious plan has been pursued.

(To be continued.)

PHOTOGRAPHY IN NATURAL COLOURS.

A CORRESPONDENT of the *English Mechanic*, referring to a notice of Captain Abney's recent experiments which had appeared in that journal, says:—

"In a recent number of the *English Mechanic* it was announced that Captain Abney, the well-known photo-

graphic scientist, had actually succeeded in photographing the spectrum in its natural colours, and as this chromo-photography has always been a favourite study of mine, I venture to lay before my readers a few theories concerning the probabilities of its future development, and will endeavour to show the possibility of taking photographic pictures from nature in their appropriate colours. Distinctive colouring, one of the essential properties of matter, has hitherto been considered as an occult chemical property, the colour of a substance being explained by stating that the substance possessed an absorbing affinity for luminous rays of a certain period of vibration, or wave-length, and after abstracting those from the white light which fell upon it, reflected the residue to the eye. This hypothesis is, however, necessarily very unsatisfactory, as it involves an unknown principle to account for the absorption. When we consider that every known substance possesses a colour or tint so peculiarly and distinctively its own that it is possible, by the use of the spectroscope, to detect the presence of the substance in a compound, it would seem that nothing short of nebulous matter, from which all substances have origin, would collectively supply their exact tints, we are forced to admit that, according to the absorption theory, colour photography, if not an impossibility, is at least an improbability.

"In my opinion, however, the present extent of research not only does not justify us in adopting the absorption theory, but even points conclusively to the truth of a theory which I am about to elucidate, and which depends solely upon known and acknowledged principles. In every case where physical conditions have enabled us to obtain bodies, no matter how opaque in bulk, in a state of extremely fine division, they have been found to be more or less translucent or even transparent. The obvious deduction to be drawn from this is that the ultimate particles of matter are transparent, the opacity and colour when in bulk being dependent on the size of the particles or molecules, and the aggregate number in the direct line of vision. Now, the only ways in which man has yet been able to create or alter colour have been—1st. By coating a substance with a layer of film of another substance possessing inherently a different colour. 2nd. By chemically altering the arrangement or size of the ultimate particles or molecules of a body. 3rd. By regulating the thickness of extremely fine films or transparent laminae. Sir Isaac Newton was, I believe, the first to show that within certain limits of extreme thinness in extreme laminae, each grade is distinguished by its power of refracting a different prismatic tint. These limits—or, in other words, those grades—of thinness included in the space between where the first faint indications of colour are apparent, and the excessively thin part where all colour, and even the reflection and refraction of light, ceases, depend on the inherent density and refrangibility of the substance which constitutes the lamina or film. This law, which Newton applied to transparent films only, holds good also in the case of the fine particles which constitutes all substances. These ultimate particles or molecules are doubtless very different in form, but an examination of the form spontaneously taken by crystals indicate that simple geometrical figures are most prevalent. The forms of the molecules, however, do not influence the general colour of a body so long as the sizes of their greater and lesser diameters fall within the limits of thinness which refract a particular colour. In short, the colour of a body depends solely on the size and refrangibility of its constituent molecules. Thus far the theory only accounts for the colour of those comparatively few substances which possess simple prismatic tints comprising rays of only one particular wave-length. Slight consideration will, however, show that it amply explains the presence of compound colours—those comprising more than one wave-length. It can easily be conceived that it is possible for a body to possess ultimate particles of two or more different sizes intermixed, or, at all events (if this be too important a postulate to grant without clear proof), that its particles may possess different refran-

gibilities. If this be assumed, we must conclude that the particles, whether differing in size or refrangibility, would refract appropriate colours, regulated thereby; and as these colours would reach the eye in combination, they would give the impression which we define as a compound colour, but which in reality has no existence except in the confused impression conveyed by the optic nerves in such cases to the brain. The tint of such a compound colour would, of course, incline more or less towards the simple tint refracted by the particles, the size or refrangibility of which predominate. On this theory photography in colours seems not only a possibility, but a probability. We have only to control the oscillation of any substance by the degrees of luminous intensity on the image produced by the camera to solve theoretically the problem. Or again, if we can control within minute degrees the thickness or refrangibility of a substance by the varying degrees of chemical action or force possessed by the different prismatic tints. But even if brought to practice, these processes would at first thought seem to possess two glaring defects—namely, if the degrees of colour were accurately reproduced, there would be no light or shade in such a picture; and, secondly, in order that we may have the compound tints, it is necessary that, by a perfect achromatic arrangement of lenses, an approximate image, so to speak, of each surface molecule should be produced, or, in other and simpler words, each particle on the surface of the object must be represented in the picture by an atom of film, which is capable of refracting the same tint. In the first case, the gradations of light and shade and outline could be obtained by superposing an ordinary monochrome positivo over the transparent chromo-photograph; a perfect picture would thus result. It is obvious that the discovery of this long-desired and ideal art will require more than ordinary ability, perseverance, and research; yet, in this case at least, the reward would be equivalent to the labour. The discovery of chromo-photography would herald a new era in this age of art, and the vision of its vast importance, and of the probable civilising and humanising effect it would have on mankind, should encourage all who, by patient research, are endeavouring to reduce its theory to practice."

"T. H. S. II."

A FEW FURTHER REMARKS ON WAVE BATHS.

BY H. J. BURTON.*

I CALLED attention in a recent number of the *Autotype Notes* to the advantage of using wave baths in place of the ordinary dipping bath for studio work. I propose now to say a few words upon the construction of them. I need not refer to the numerous trials made in this direction and extending over some years, but any one who has given attention to this subject knows the difficulties to be overcome to prevent leakage in made-up vessels.

The improved bath as now made is essentially a wood case, lined with canvas, and rendered waterproof by a cement, which is spread with heated irons, at the same time attaching the canvas to the wood case in the most perfect manner, so that should the case at any time crack, no leakage would occur, as freedom from leakage does not depend upon the case, but upon the lining, the cement being elastic as well as waterproof.

Pine is undoubtedly the best wood to use for making the case, on account of its lightness, porousness, and least liability to expand or contract; it should be of such a thickness as not to "give" when roughly handled. The back should be framed and paneled, and care taken that the panels be loose, so as to allow for expansion or contraction. The sides and ends are best put together with double dovetails the whole width of the pieces of wood, so ensuring a very strong frame without either nails or screws.

The canvas is applied to the back, the frame, and the well-piece separately; they are then put together with wood

* *Autotype Notes*.

dowels, and the junctures made good with a fillet of cement applied hot, and finished off with a hot iron rod bent to a convenient shape. At the upper end of the bath an ebonite tube is inserted, to allow the contents to be drawn off; and a row of ebonite pegs is inserted in one of the styles, near the lower end, upon which the plates are supported when placed in the bath, and while being drained. A light frame covered with two thicknesses of leather cloth, placed so that the two unprepared sides come close together, makes a close-fitting cover, and which is supplied with lifting hinges to allow of its removal for cleansing purpose. On the sides of the bath, at a convenient place, are fixed a pair of centres, so placed that, when containing the solution, it will lie in a horizontal or nearly vertical position, by simply placing it in the position required, no support being necessary beyond the cradle, which takes the general weight of it.

As long as the wet collodion process is used, I am confident that these baths will continually grow in favour with professional photographers. The only thing necessary to ensure this is being able to get a reliable article for use.

In answer to some remarks that appeared in one of the journals, as to this kind of bath producing stains and oyster shell markings, I may say that in the Autotype Company's studios they are exclusively used from small 12 by 10 to 7 feet size, and no troubles of this kind ever occur; in fact, it would be simply impossible to turn out any large quantity of work by means of ordinary dipping baths.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER III.

NORTHWARD HO!—HOWIE FEELS GOOD!—PHOTOGRAPHING A CORPSE.

GILBEY, the head man in the expedition, proved to be exactly what the traveller had described him, a taciturn, silent man—a sort of domestic Diogenes, who looked upon speech as superfluous, or so much breath wasted, and who had reduced his language to monosyllables and signs. Fahey the difference between him and Howie—the one all chatter and noise, sparkling and fresh as a brooklet; the other calm, silent, and unfathomable as a deep lake. During their first meetings they used to eye each other in curious amazement. The volatile rattle of the one, and the brooding silence of the other, were sources of vast speculation and deep thought to each other. Gilbey would listen to Tom with open eyes and mouth, while his inner thoughts were no doubt bent upon solving the problem of how such a quantity of garrulity could be encompassed in one head; while Tom, in the midst of some wonderful escapade, would catch his eye and instantly stop short, and commence a long and silent inspection of him, after the fashion you see people look over some *rara avis* or wonderful relic in a museum. Yet, although their natures were so opposite, I am convinced that they had a great and real regard for each other; in fact, we were all well suited for each other, and never had an unpleasant word until Tom and I fell out on board of ship on our return voyage: but of that I shall inform you on a future occasion.

We were three days at Ardrossau waiting for the freighted steamer to arrive from Liverpool with the noble company, and busied ourselves by overhauling our traps. I do not think that at any other time in my life did I ever see such a conglomeration of photographic requisites as that which Gilbey had gathered around him. We had gallons upon gallons of bath secured in huge jars covered with wickerwork, hundredweights of iron, and about a ton of glass. Had we been going to photograph the whole world we would have had some left over to commence upon the moon and the stars. Gilbey was told to take plenty material with him—and he did it.

At length the steamer arrived, and amidst a Highland yell from the ragged urehins on the beach, we went on

board—bag and baggage—and before night fell we were steaming Northward Ho! Sweeping through the darkling waves with music, song, and laughter floating around us, with the moon peeping over the crest of the distant Ben Lomond, silvering the water and lighting the shadows on the Kyles of Bute, was it any wonder that we were happy—that a tinge of romance should spread itself over our feelings like honey on a sweet cake?

"Ah, Geo!" sighed Tom, as we leant over the bulwarks and enjoyed to the full our position, "this is something like. This is what I have panted for, for years. I don't know how it is, but this scene has an awful effect upon me. I feel better; yes, I do—I feel regular out and out good. Now I can realise the fact that it is a sin to steal a pin, to lie, to cheat, or otherwise behave like a blackguard. When first I came on board I must honestly say that my feelings were those of a pirate, and I found myself casting up the chances of raising a mutiny among the seamen, consigning the noble lords to a watery grave, taking sole command of the vessel, and becoming the scourge of the seas. But it is different now. I feel good and brave and noble. I am at peace with all the world. I freely forgive all whom I have injured in word or deed, and bless them into the bargain."

How many are there whose magnanimity ends in the same way!

"Yes, I have not felt so well since the shock I received when I was with Carey."

This Tom addressed to Gilbey, who had joined us. Gilbey looked an inquiry, but not a syllable passed his lips.

"What shock was that, Tom?" I asked.

"An awful affair that happened some time ago," quoth Tom; "a strange affair, and perhaps you won't believe it; but I will tell it to you all the same. You have both heard of Tim Finnigan, I daresay, the Irish gentleman that carried the hod. Well, Snooks was a slater with the same amiable weakness as Tim—he used to like a drop of the *cratur* of a morning. Snooks, independent of this failing, was a neat, dapper little man, and, I believe, was very clever at his business. One thing he used to pride himself upon was the unble way he walked the roofs; he was proud of his talent in this way, and used to take every opportunity of showing it off. People used to gaze at him in admiration and terror. The boys used to follow him about, and would rather see him run along the ridge of a roof than go to the circus. He was a regular hero in his way, I assure you. But pride is sure to have a fall, and so had Snooks. One day he was employed to repair the roof of an old lady's house in the suburbs. The roof of this old lady's house was built at a very acute angle, with two very old-fashioned attic windows starting out from it. There was no blame that could be attached to the old lady, for I was told that she cautioned him strongly not to run along the ridge in his usual reckless manner. But Snooks, apparently, was humau, and of course did not take the good advice. How it happened I cannot tell—whether it was a drop too much, or a more than usual decayed roof—but there was a rattle and slip, and a noise like a horse coming downstairs. The old lady, who had followed him upstairs, had just time to rush to the window, and see him go past. He saw her, however—smiled—waved a feeble adieu—gasped, 'What a devil of a fall I'll get!' and disappeared over the edge of the spout."

"Come, draw it mild, Tom."

"Sir! Mr. Gilbey, is that fair? He is always insinuating and doubting my veracity. And if he does that at the beginning, what will come of him at the end?"

Something like a chuckle was Gilbey's answer.

"No, Geo!" continued Tom, "I told you before that I felt good—that I felt far above the weaknesses that flesh is heir to. Snooks fell in the manner I have described, and Snooks died from the injuries received in

that fall, and according to the usual run of things I should have been done with Snooks for ever. But not so. Two days after his decease old Carey came into the studio in a state of unusual excitement. 'Aha Tom!' he cried, 'we have got such a rare job. You know Snooks the slater? Well, his old mother has discovered that he never had his picture taken—in fact, that she will have nothing to remember him by; and as he was the only relation that she had, she is determined to have him photographed as he is.'

And so it was. Old mother Snooks felt, at the age of sixty, that she was bereft of all her kith and kin—in short, that she was an out-and-out orphan, and was determined to have a picture of her son to console her during her remaining years. Pleasant or unpleasant she did not care, so be that it was a picture of her son.

Snooks had first been taken to a hospital, and thence to his mother's house, a little old-fashioned cottage, situate on the edge of a dreary moorland. To this place Carey and I went on the following morning. I said that I received a shock on this occasion; but I should have said, a series of shocks. First, I was shocked at the bare idea of having to participate in the nasty job; and shock number two was administered when Carey and I went to metamorphose an old hen-house into a dark-room. While we were grubbing around and putting things in order, a rustling in a corner attracted our attention.

"What's that?" cried Carey.

As he spoke, a long neck, looking ever so long in the uncertain light, was reached out towards us, on top of which gaped a pair of jaws, and above the jaws a pair of fiery bead-like eyes. This apparition hissed and blew in an awful manner.

"Ye gods! It's a serpent!" shouted Carey, as he bolted out of the hut with a terrific yell.

His cries brought Mother Snooks and the rest of the mourners to see what was ado. Then it transpired that they had forgot to inform us that there was a goose in that corner sitting upon eggs. You may laugh, but I can tell you it shattered our nerves awful, and we had to get some of Mother Snooks' whiskey before we tackled the job again. At last, everything got into fair sailing order, and with a plate in the dark-slide, we entered the chamber of death. Poor Snooks was there all right—as quiet and still as you need wish, and with rather a knowing look upon his rigid countenance.

"Now we must have him hoisted," quoth Carey, cheerfully.

"What?" cried Mother Snooks.

"I say we must hoist him up a bit," replied Carey. "You see, in his present position we would only get a picture of his nostrils—his nose would be abridged—his features shortened."

Then Mother Snooks lifted up her voice and gave him the word of denial; she dared him to touch a hair of her dear son's head: she called him names, and appealed to her friends that she said as much that he was no man when he would be frightened at a poor goose: he did not know his *business*, and if she was his wife she would take the broomstick to him. In vain did Carey and I expostulate and explain the absurdity of photographing the holes in Snooks' nose; she was as firm as adamant, and it was only after a good application of whiskey that her friends wrung a slow and surly acquiescence to the putting of a chair under the head of the coffin. Now this was a highly dangerous plan of hoisting him, and I pointed it out to Carey, but he merely pooh—poohed, and said it was all right.

Everything ready at last; the company crowding in breathless silence round the door; Snooks self-possessed and calm; the shutter was drawn; the cap about to be taken off, when Carey cries sharply, in his professional voice, "Steady, please!"

This caused the company at the door to start—the start shook the floor—the table creaked, and whish! over tipped

the coffin on to the floor. Gentlemen, that was the only time I ever had the horrible pleasure of feeling my hair stand on end!"

With one united cry, the company, headed by Mother Snooks, turned and fled. Carey dropped down in a dead faint when he saw the moving mass. So there I was left the only sensible man in that awful chamber. I ask you honestly if that was not a shock to hurt a man's health? It was a blessing that Snooks fitted his coffin so well, for it didn't spill him in the least, but tipped over him, bottom up, as neat as you like.

Although horror-struck at the scene, I kept my presence of mind, and rushing for the whiskey bottle applied it to Carey's lips. The effect was miraculous: he grangled, gasped, winked, and reached after the bottle like one o'clock.

"Where is he?" he gasped at length.

"Who?"

"Why, old Snooks!" answered Carey, looking suspiciously around the room.

"Here he is," I answered, tapping the bottom of the coffin in a reassuring manner; "safe and sound."

"Where's his mother?" asked Carey, feeling the back of his head.

"The Lord knows," I answered.

Then we went to the door, and looked forth; the nearest relative (with the exception of the mother) was at least a quarter of a mile over the moor, and making the best running ever they did in their life. The mother was sitting on a big stone about two hundred yards from us, shouting "Police!" and "Murder!" in the most maudlin manner.

"Now is our chance, Carey," I cried; "let us go back and hoist him up to our own content, and the job is done."

We did it; we photographed him in dead silence. We developed him in the hen-house amidst the hissing and blowing of the disturbed goose, and came forth with the negative in time to meet the mother and the relatives returning from their outing.

A fair allowance of whiskey seemed to fetch all our levels, and we would have parted friendly if it had not been for Carey's hat.

"Why, what about it, Tom?" I asked.

"Why, you see," quoth Tom, "when he came to try it on, it would not fit, so he swore that it was *not* his. He offered to fight any man who dared to say that it was his, so all the men who possessed tall hats silently passed over their beavers to him to try on, but none of them would fit."

"Why, how was that?"

"Why, when he fell down in the faint, he knocked his head on a corner, and raised a bump on it like the hump of a camel, so, of course, his hat wouldn't fit; he had to wear it far back on the lump, or over his eyes; but to this day you can't make him believe other than that some one swindled him out of his hat. What do you think of that for an adventure?"

Neither Gilbey nor I spoke, so Tom, after eyeing us for a minute or two, started off again. "You think it wonderful! So it is, but I can tell you more wonderful tales than that —"

"Oh, oh!" gasped Gilbey, "Mercy! Help me below—I faint—I die!"

"Do you want to kill us, Tom?" I cried, reproachfully.

"Do I want to kill you?" repeated Tom, scornfully.

"Some people can stand nothing! I'll go to those who can appreciate my genius."

So Tom went forward to the galley to harrow up the souls of the seamen, with whom he was on friendly terms already.

DETAINING OPERATORS' SPECIMENS.

DURING the score of years, or nearly, we have had the Editorial charge of this journal. We have been in constant receipt, at intervals, of complaints from operators that specimens, sent as examples of their work in reply to advertisements, have been detained, no pressure serving to secure their restoration. In some of the cases into which we have had opportunity of making enquiry, we have found that the detention was due to the carelessness of the sender, who had failed to send an address! In some, he had failed to put any name or distinctive mark on the specimens, and in the haste of opening several similar letters, the specimens had got mixed without presenting any aid to sorting them; in some, to the absence of an addressed and stamped envelope, when the advertiser—churlishly enough, it must be admitted—declined to address and stamp a dozen or a score of envelopes for the purpose of sending back what appeared to him valueless specimens.

But there are, there is too much reason to fear, some cases in which some good specimens are appropriated because they possess some value or interest.

We have just received a complaint from a correspondent, of twice being treated in the same manner by the same person, which gives the circumstance a deliberate, if not a systematic air. Here is the letter, with the name omitted, in deference to the uncertain character of the English libel laws:—

"Some time since, having occasion to advertise in your columns for a situation as assistant, I received a reply from * * * of Sherborne, requesting me to send carte of self and specimens of my work, which I at once did. I then received another letter asking if I was capable of undertaking retouching; this I answered in the affirmative, but neither received a reply nor my specimens, and heard no more from him until last week, when he again answered an advertisement of mine requesting specimen. I then wrote him asking him to return the ones he had previously received, but can get no reply. My object in asking you to insert this is, that any who have been treated in a like manner may communicate with me with a view of taking steps to put a stop to this shameful system of obtaining specimens, and in many cases from those who can ill afford to part with them.—I am dear sir, your respectfully,
"C. W."

We think that whether such detention of specimens arises from carelessness, churlishness, or dishonesty, the cruelty it involves can never have occurred to the perpetrator. An operator applying for an engagement, without the means of showing the quality of the work he can produce, is helpless indeed, and must often remain so.

It is, we fear, very little use to appeal to those who neglect to return such things through carelessness, as care-

lessness is an unconscious fault which few men, however careless, admit, or recognize in themselves. The remedy chiefly rests with the operator in dealing with his specimens. Let him work across all of them—say on the back-ground—his own name, so that they cannot be exhibited as the work of some one else. Let him also place them always in a stamped and addressed envelope, so that they can be returned to him without trouble. And let him carefully avoid sending all he possesses to any one man. With these precautions duly regarded, there would occur few occasions for complaint, such as that so legitimately made in the above letter.

THE ALLEGED EARLY PHOTOGRAPHS.

THE persistent vitality of an error is amazing. Everybody interested in photography remembers the long investigation devoted to some old pictures alleged to be photographs, discovered in Watt's house at Soho, Birmingham. The basis of the supposition that they might be photographs consisted in the fact that they were monochromes, they were copies of paintings, and were manifestly by a process of multiplying, as there were several duplicates of some. That they were not photographs was manifest for several reasons, one being sufficient, namely, that the duplicates were not identical, as, if printed from a cliché, they must have been. Despite the decision of various capable investigators, we find in *Muyfair*, a generally well informed journal, a paragraph like the following:—

"Sankey's way of securing immortality—going down to untold ages as a voice singing 'Hold the Fort!' on a piece of tin-foil, sealed up in a foundation stone—is not a bad notion. Only, by the time the future generations find that hieroglyphic scrawl, the chaucers are the phonograph will have been forgotten, and its turn for being re-invented will be coming round again. I am haunted by the recollection of those photographic negatives that were found behind the wainscoting of James Watt's room, a hundred years after he had hidden them away. Photography had been discovered, forgotten, and then discovered again as a perfectly new thing."

Apart from the revival of the general error, we may remark that there never was either supposition or allegation that the pictures were negatives, and they were found amongst the rubbish stored away in an unused room at Soho, not behind the wainscoting of Watt's room. We may as well quote another paragraph from the same writer, as it refers to photography, and contains another curious error. Here it is:—

"Photography leads me to mention Sarony, the famous Scarborough artist, who died last week in the prosperous town he had done so much to make. I remember Sarony thirty years ago, before he found his way to Scarborough and a fortune. He travelled in a handsome caravan from town to town, popularising the Daguerreotype. Sun-portraiture on glass had not been recovered then from the strange oblivion to which Jammy Watt had consigned it. A quarter of a century makes a vast difference to some men. Now there is Sarony Square, and all the world has seen the handiwork of the tall, handsome man with the long flowing beard."

It is perhaps scarcely worth remarking that Sarony, truly a handsome man, with a long flowing beard, a splendid chest and shoulders, the torso, in fact, of a giant, was not a tall man, but slightly under middle height.

FRENCH CORRESPONDENCE.

MAGISTRATES AND PHOTOGRAPHERS—PHOTOGRAPHING THE NATIVES—DRY PLATES OF GELATINE.

Magistrates and Photographers.—Magistrates seem likely to occupy an important place in the chronicles of photography. The ridiculous spectacle that one of them made

of himself the other day, when he ordered the name of a photographer to be struck off the jury list on the ground that no photographer was sufficiently intelligent to consider a criminal verdict, appears not to be an isolated case. A similar incident, in which parts were played by a magistrate and a photographer, happened the other day at Paris, and deserves to be widely known. As is no doubt the case in England, the portrait photographers of reputation here request all their customers to pay the amount of their orders before allowing them to be taken. This is a regulation to which the public is well accustomed, and to which it submits quite willingly, knowing that every well-bred visitor will conform to the rules and customs of an establishment to which he repairs at his own inclination. With this view, also, it is always customary to have written up in large letters, in some conspicuous place where the orders are taken: "Customers are requested to pay before being taken." In the house where the incident we are about to relate happened, this notice was written up in four languages on a window frame on one of the Boulevards; no one, therefore, could plead ignorance. However, a gentleman one day lately presented himself at the office of this establishment, leading by the hand a pretty girl, of whom he desired to have a photograph taken; and after he had made choice of the style and size he wished for, he was politely requested by the young lady who booked the order to be good enough to settle the amount. But though she directed his attention to the notice on the window frame, his hand did not seem to be finding its way to his pocket, and as he appeared to pay no attention, it became necessary to repeat the request several times. This attracted the attention of the proprietor of the establishment, who was just engaged in taking the orders of a celebrated personage; and when the latter, without any reminder being necessary, bent his steps in the direction of the cashier with the object of discharging his account, the former turned to his dilatory customer, and, with a courteous movement, observed, "You see, sir, all our visitors do not require to be asked to conform to the rules of the establishment." "Have you, then, the pretension," asked the visitor, "to require payment before you deliver the goods?" "It is the custom of the house, sir; you may see by that notice that no one is deceived." "But if you cannot place confidence in me, why am I to trust you?" "No one compels you to come to me, sir." "Well, then, I will pay; but it is understood that I have a right to refuse the goods if they are not in accordance with my order." "Certainly, sir; our clients are too distinguished for us to offend them." With this hint the proprietor left the room, while his unknown customer proceeded to pay his account with an ugly look of discontent on his face. Fortunately, it was his lovely little girl who was to be taken; if he himself had been sitting, the camera would have rendered an expression of countenance which the photographer might have labelled with justice, *Le quart d'heure de Rabelais*. "It is then agreed, mademoiselle," said the stranger, after pocketing his purse, "that I have the right to return the photograph of my little girl if it is not successful?" "Certainly, sir," replied the cashier, "you need be under no apprehension. Will you be kind enough to walk upstairs into the studio?" "Here is my card, mademoiselle," said the gentleman; and on glancing at the card, in order to enter the name and address of her troublesome customer, the cashier was doubly astonished to see that the originator of this little scene (the like of which she had never experienced since she had presided at the pay-desk of her employer) was a M. A.—, *Juge de Paix*. The magistrate's child was duly photographed with all the ease which so little amenable a visitor would be sure to command, and after the sitting the operator, not without some stiffness, said: "You will receive a proof, sir, the day after to-morrow."

Of course, it will be at once guessed that under such circumstances the most successful proof that had ever been secured would be sure to meet with the indignity of a

refusal. "Give a dog a bad name, and hang him." The next day the magistrate reappeared, and with a coldly-polite air, handed back the admirable likeness of his little heiress (let us hope, for the sake of her future husband, that she does not inherit her father's character). "I bring back your proof, sir," he said to the operator, whom he had caused to be disturbed and fetched away from his work; "it is not good. Tell them to return my money." "Will you allow me, sir?" replied the artist. "This proof is a success in every respect. However, if you wish it, we will take another. Only permit your little girl to sit again, and we will do our best to satisfy you." "Not at all! Not at all! I have already warned you. Return me my money; you told me I had the right to refuse the portrait." "Quite true, sir," replied the photographer, "but that was in the case of a failure. I will do the work over again, in order that I may be completely justified, but I will not return you your money unless a competent judge will declare that the photograph I have sent you is really a bad one." "Very well, sir; you refuse to keep your engagements, and you shall hear from me." "I shall be glad to do so, sir," said the photographer; but before he could utter the words, the magistrate was already lost among the crowd on the Boulevards, with such haste did he descend the stairs, dragging with him his little girl, whose eyes were wide open with astonishment.

The next day the photographer received a stamped paper. The magistrate had summoned him to appear before a colleague of his own, the magistrate of that special district of the city, as an arbitrator. Before this Court, relying on his official position, he had made arrangements to bring his photograph and his complaints, although by doing so in this way he kept more than a hundred persons, who really had a prior right to be heard, waiting for an audience. He expounded his case at full length, and concluded by demanding the repayment of money paid in advance for goods refused as not being according to the order. The photographer, in reply to the magistrate before whom he had been summoned, stated that he was very sorry to keep so many persons waiting with business, probably much more important than this, for he had nothing to say further than to repeat his offer to execute the portrait again; he added that he denied the competence of the tribunal before which he was cited, and that he would only submit to the decision of a photographic artist. The arbitration having thus fallen through, the case was remitted to another Court. Here the plaintiff pleaded that no one could better than himself form a judgment as to the resemblance of a portrait to his own child; that he declined to be the victim of the arbitrary regulation of a house of business which, in the interest of justice, ought to be abolished. But the photographer, firm as destiny, and immovable as his own camera, stuck to his text: "I do not admit the competence of this tribunal; I demand an expert." The judge, not having a precedent at hand, and really not knowing how to get out of the fix into which his colleague had forced him, at last gave utterance to the terrible words: "I nominate such and such a photographer as expert." Tableau! The photographer left the Court as radiant as the morning star, the plaintiff with his feathers ruffled like a hen who has had a narrow escape from a fox; and, in fact, this magistrate, who had wished to be at the same time judge and plaintiff in his own cause, never afterwards put in an appearance. He gave up his money and waived the right of having his photograph taken again—all which is a matter of course.

Now, this little story, which is really and strictly true, affects, perhaps, more than at first sight appears, the question first mentioned of the magistrate who refused to allow the name of a photographer to be inserted on the jury list. Perhaps the same man is the hero of both narratives; this would at once explain why he regarded a photographer as a person devoid of intelligence, because he had once met one who possessed more than himself.

(To be continued.)

GERMAN CORRESPONDENCE.

BY DR. VOGEL.*

DR. SCHULZ-SELLACK DECEASED—THE PURPLE OF ANCIENT TIMES A NEW PHOTOGRAPHIC SUBSTANCE—SENSITIZING ALBUMEN PAPER BY IMMERSING—THE LATEST ABOUT GELATINE PLATES.

ONE of our contemporaries recently expressed regret that there was nothing heard any more from the renowned German photo-chemist, Dr. Schulz-Sellaek, and it was evident that the writer of the paragraph was ignorant of the fact that at that time the Doctor had been dead for some months already. He died in May of this year, having taken poison, together with his adopted father and his mother. All three had been living formerly in pretty comfortable circumstances, but by-and-bye they became reduced, step by step, and when the last had gone, they committed suicide. It is to be deeply regretted that the departed man of science kept his misery locked up all within himself, as otherwise his friends would cheerfully have helped him to bridge over his momentary difficulties. Dr. Schulz-Sellaek was not unknown in America. He went to New York in 1871, after having published some very interesting papers upon the photography of the spectrum, and the relation between absorption and photographic effect. He assisted Kurtz, in New York, as retoucher for some time, and went with Gould, in 1872, to Cordoba, Argentine Republic, from whence he returned to Berlin, where he occupied himself with studies relating to the natural sciences. His old friends and colleagues seldom got a glimpse of him, and only the notice of his death drew general attention to him once more. The last fruit of his researches published by him related to bromo-silver paper. He found that bromo-silver could be used in the positive process just as well as chlor-silver. Bromo-silver paper, by itself alone, however, gives only weak pictures, and it is only after fuming with ammonia that it prints really beautiful and brilliant, and also much faster than chlor-silver paper. Upon his recommendation bromo-silver paper was practically tested, and the fact was thereby established that the making of chlor-silver and bromo-silver produced extraordinary brilliant pictures. In spite of all, the papers did not prove a success in practice; their extreme sensitiveness proved to be more of a drawback than an advantage, for they require special thick negatives, that the lights might remain white. One of the most interesting observations made by Schulz-Sellaek is the dissolution of the crystals of chlor-silver, bromo-silver, and iodine silver in the light. He prepared plates of so-called vitreous iodine silver, which were quite diaphanous, but became dull in the light. He even copied pictures on such plates, and it thereby was observed that according to the relative intensity of the light, curious colours appeared, which phenomena he made mention of in explaining the coloured photographs of Poitevin, Niepce, &c. Dr. Schulz-Sellaek left no papers behind him. He declared all of them to be worthless, and burned them up. What a pity that the untiring, highly-gifted scientist had to speak thus despondingly.

One of our younger chemists, Dr. Schnuck, who occupies himself much with experiments on alizarine, published recently an interesting work upon the purple of the ancient times, and according to these experiments, this in olden times so much desired and praised colour seems to be a photographically interesting substance. It is the secretion of the purple fish. Schnuck writes:—"When a piece of white linen is soaked in this stuff, and exposed to the light of the sun, the originally yellow stuff changes from green and blue to purple or scarlet, while a strong garlicky smell is emitted. Daylight is absolutely necessary to the formation of these colours. In the dark this stuff remains unchanged for years. The colour is not affected by alcohol, soap, or acid; only chloric acid or nitric acid destroys it,

and we have here a dyestuff which, contrary to the rule obtaining with most other dyestuffs, not only does not fade in the light, but actually gains in intensity. The stuff is much less affected by corrosive substances than most other similar dyestuffs are, and we have in it a substance which answers the most severe requirements in regard to durability which can possibly be made. If it were possible to gain this stuff in larger quantities, the problem of producing durable photographic pictures would be solved in the most simple manner." Schnuck states that from four hundred pieces (*Purpura lapillus*) he obtained only two milligrammes of the purple powder. But doubtless the purple-fish in the Mediterranean will yield more of the stuff, as otherwise the ancients could not have used the same in such considerable quantities. It is surprising, however, that the photographic properties of this interesting substance have not been discovered till now. Schnuck classes this dyestuff (which he calls "Punlein") among the indigo group, and as indigo has been produced already through artificial means, it is not improbable that also this dyestuff may be obtained through artificial means some day, and then its use for photographic purposes will be assured, although the smell—resembling the strong smell of garlic—which is emitted in printing may not be a very acceptable and pleasant addition to the other pronounced smells for an elegant atelier.

It has lately been recommended here to sensitize albumen paper, not in the old way of floating on the silver bath, but by immersing in the silver bath. A paper is obtained thereby which is more than three times as sensitive as ordinary paper, and printing at least just as brilliantly.

The gelatine plates are yet much talked about, and it is now a pretty well-established fact that they are gaining more and more ground in photographic practice. In summer, of course, when we have plenty of light, we do not need those highly sensitive plates; but we want them the more in winter, and it is certain that the winter is the real favourable season for the gelatine plates. They are handled easily then, while in summer their proper use meets with many difficulties, as the most recent experiences demonstrated. The gelatine skin softens and wrinkles, &c. Obernetter adds some isinglass to the gelatine to avoid these annoyances; but the best is to apply cold water, and the ice-pitcher seems to be destined to become an indispensable requisite for the dark room in case the gelatine process is introduced into summer practice. Obernetter tried, some months ago, to introduce liquid gelatine emulsion into the market, but the same did not prove a success. In summer it did not keep, and now Obernetter has replaced it with solid emulsion, as did also Kennett. While with other plates, insufficient sensitiveness proves a drawback, it may happen with gelatine plates that the over-abundance of sensitiveness works disaster. When I am experimenting with gelatine plates in summer, I have to shut off my whole studio, with the exception of an aperture of about fifty square feet, in order to prevent over-exposure, and yet I must not expose more than from three to five seconds. In out-door work the instantaneous shutter is quite insufficient, and it would be a grateful task for the skilled mechanics to construct an instantaneous shutter, working quick, without shaking the objective. It is probable that if the gelatine plates come into general use, large and costly objectives will be dispensed with, and we can then easily work with the smaller and cheaper apparatus of Steinheil, or with the rapid rectilinears.

THE SUPPOSED COMPOUND NATURE OF THE ELEMENTS.*

BY J. NORMAN LOCKYER, F.R.S., ETC.

CONTINUING my researches into the nature of the so-called elements, I have found that when carefully distilled metallic

* *The Philadelphia Photographer.*

* Read before the British Association for the Advancement of Science

sodium was condensed in a capillary tube, placed in a retort, and heated in a Sprengel vacuum, it gave off twenty times its volume of hydrogen. Phosphorus, carefully dried and submitted to the same treatment, gave off 70 volumes of a gas which appeared to consist chiefly of hydrogen. Although it gave some of the lines of phosphorus, it was not P_{113} , as it had no action on solution of cupric sulphate. A specimen of magnesium carefully purified by Messrs. Johnson and Matthey gave me a magnificent series of coloured phenomena. The hydrogen lines first appeared, then the D line—not the sodium line, be it understood, for the green line was absent—and, lastly, the green line of magnesium (*b*) and then, as the temperature was increased, mixtures of all these lines, with the blue line, the D line being always the most brilliant. In this experiment only 2 volumes of hydrogen were collected. From gallium and arsenic no gas of any kind was obtained. From sulphur and some of its compounds sulphurous anhydride was always obtained. From indium hydrogen was given off in vacuo before heating, while from lithium no less than 100 volumes of hydrogen were given off. The conditions of the experiments were always the same, the only variable being the substance itself.

Correspondence.

LUXOGRAPHIC PICTURES AT FALMOUTH.

SIR,—In your last issue, containing report of the Cornwall Exhibition, I am placed in a very unfair position by the judges' report, and also by your correspondent.

The pictures referred to were from negatives taken at a fancy dress ball, a few months ago. During the night of the ball I exposed one hundred and fifty cabinet gelatine plates, and obtained one hundred and forty good negatives. Knowing I was so successful, the manager of the Luxograph Company asked me for a few prints as proofs of the good work that can be done by the luxograph, and I suppose sent those to the Exhibition, with other work by different photographers, merely to show the kind of work that could be done by night. At least, this is the construction I put on the matter, and trust to find this stated in your journal for their own sake as well as my own, for I do not like to be suspected of having done what I trust no photographer ever has done or will do—viz., to attempt to obtain an award for work not done by himself.

May I be allowed to say that all the negatives referred to were exposed and developed by myself, hence the photographs looked upon so dubiously were my own production.—Yours truly,
J. S. HAZARD.

PS.—I enclose a few of the specimens for your criticism.

[It was unfortunate both for Mr. Hazard and the Luxograph Company that a previous understanding had not been acquired before sending in specimens. The examples exhibited are very highly commended, and that worthily, both by our representative and by the judges. The prints, some of which are before us, afford high testimony to the efficiency of the lighting arrangement, and to the photographs being, as alleged in our last, scarcely inferior to wet collodion pictures.—ED.]

THE following letter has been addressed by the Luxograph Company to the Judges of the Royal Cornwall Polytechnic Exhibition, photographic department:—

"GENTLEMEN,—We notice in the report of the above exhibition, that you (the judges) call special attention to some fine examples of portraiture taken at night by means of the Luxograph process, &c., but owing to the same pictures having been sent by two exhibitors, you (the judges) are unable to make any award. We therefore feel it neces-

sary that we should at once explain the reason of this occurrence, and thus call your attention to a decided miscarriage of justice.

"We, as manufacturers of the apparatus, exhibited two frames of Luxograph pictures, also an album, to show the results obtained by different photographers who are using the instrument, and not as the photographer or as our own pictures, and they were thus labelled 'Luxograph Portraits (Alder and Clarke's Patent).' The pictures in the album were arranged so that the photographers' names could be seen, and were exhibited with the full consent of the different producers.

"The award, therefore (if any), is clearly due to Mr. Hazard, who exhibited a frame of Luxograph pictures as examples of his own work and also as specimens of fine photography produced at a fancy dress ball by means of the Luxograph patent. If any award had been made us for the photographs it must have been returned, for the only one we could accept would be one for the invention or process now known as the Luxograph.

"We feel sure that this explanation of the circumstances will enable you to rectify the matter, and that Mr. Hazard will not suffer through having accidentally presented us with some of the same subjects as he himself exhibited, for there were 150 excellent cabinet negatives out of 155 taken on that particular night, and, therefore, no dearth of regalias or subjects to select from.—We have the honour to be,
"THE LUXOGRAPH CO."

[There can be little doubt, we think, that the medal in this case is due to Mr. Hazard. We fear, however, that after the judges have separated, believing their work done, there is little chance of a reconsideration of the case. We should be glad to learn that the judges had set aside difficulties in order to secure justice.—ED.]

DEAR SIR,—Seeing in your special correspondent's report that Mr. Hazard and the Luxograph Company exhibited prints from the same negatives—hence no award was made—one is tempted to ask a question with reference to the medal awarded to Mr. H. G. Cocking's enlarged group of the members of the South London Photographic Society. Had Messrs. Wratten and Co., who prepared the gelatine plate upon which it was taken, and the Autotype Company, who made the enlarged negative and print, also exhibited prints, who would have been entitled to the medal, or would there have been "no award," as in the case mentioned by your correspondent?
NOT AN EXHIBITOR.

[Our correspondent hits an important blot. Where a result is produced by collaboration, it becomes very difficult to decide the legitimate claimant for the honours of production. Probably the judges would do their duty in awarding to the exhibitor. It is scarcely their duty to make detailed enquiries as to the real producer.—ED.]

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN EXHIBITION, 1879.

DEAR SIR,—I am requested to ask you to allow me to remind intending exhibitors that Friday, September 26th, is the last day appointed for the reception of pictures—by packing case, to Mr. Bourlet, 17, Nassau Street, W.; and by hand, at the Gallery, 5, Pall Mall East.

Any further information will be supplied on application to,—Yours faithfully,

EDWIN COCKING (Assistant Secretary.)
57, Queen's Road, Peckham, S.E.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE first meeting of the session took place on Thursday, the 11th inst., Mr. C. ADIN, President, in the chair.

After the minutes of the previous meeting were read and confirmed,

The SECRETARY read the resignations of Messrs. John Frankland, F. G. Yorston, David Young, William Griffiths, and M. Noton.

It was proposed to make Mr. Noton an honorary member of the Society, which proposition was accepted with acclamation.

Mr. W. J. CHADWICK (Secretary) then read a paper on "Photographic Societies," advocating more interest, energy, and management, with various suggestions of how to obtain these. A discussion followed.

Mr. W. G. COOTE brought before the meeting a splendid collection of negatives by the collodio-albumen process, and many by the gelatine process.

Mr. W. B. WOOD exhibited a quantity of photographs from collodio-bromide emulsion negatives.

The SECRETARY showed a few gelatine negatives, quarter-plate size, and two 15 by 12 enlargements from the same small negatives. He also exhibited two instantaneous shutters, and explained their action.

Mr. JOHN CHADWICK also exhibited an improved instantaneous shutter.

Messrs. Wade and Wright were proposed as auditors for the Treasurer's accounts.

The nomination paper was passed to the members for officers to be balloted for at the annual meeting in October. The meeting was then adjourned.

PHOTOGRAPHIC SOCIETY OF IRELAND.

A MEETING of this Society was held at the Queen's Institute, on Wednesday the 10th inst., Professor BARRETT, F.R.S.E., in the chair.

The minutes of the former meeting having been read and confirmed, five new members were elected.

Mr. J. V. ROBINSON read a paper, principally intended for the guidance of beginners, on the "Amateur Practice of Photography." At the conclusion, an animated debate took place on many of the points raised, especially the sizes of the cameras and plates desirable for the average amateur.

The CHAIRMAN then called on each member who took part in the recent excursion of the Society to Powerscourt Waterfall to produce the results of his day's work, and to explain and exhibit the failures.

The negatives and prints shown having been fully inspected and criticised, the result of the day's outing was generally considered most satisfactory, each member having secured several fine negatives as a souvenir of the first excursion of the Society.

The meeting then adjourned until Wednesday, the 8th of October.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY.

At the meeting of the 20th of June the chair was taken by Herr PRUMM, as, in consequence of having injured his foot, the President, Professor H. Vogel, was unable to be present.

Herr O. HEIM, of Grimmen, sent a receipt for making a durable paste. He takes 20 grammes of wheat starch, and makes it into a stiff paste with a little cold water; then he pours 100 c.c. of boiling water all at once—not gradually—into this paste, and stirs it rapidly. A little carbolic or salicylic acid is then stirred in, and a paste is obtained which will keep indefinitely (or at any rate until it dries up) in a cool place.

Several of the members present remarked that they were in the habit of preparing paste in the same way, and found it very good; but

Herr ROLOFF observed that care must be taken to have the best starch, as good paste could not be made with the inferior kinds.

Herr BOLL stated that he found paste to stand very well when kept under cold water.

Herrn BOLHOEVNER and HEIDENHAUS, of Munich, submitted their patent process for producing collotype plates in high relief; but

Herr SCHAIL expressed a fear that by this process the most delicate parts of the relief were liable to spoil, as, according to the description which had been given, the soft places in the

plate, where the light had not acted, were wiped away with a soft cloth cushion,

Herr HARTMANN, of the firm of Loescher and Petsch, exhibited a collection of photographic portraits and genre studies. Contrary to the usual practice, Messrs. Loescher and Petsch take some of their pictures of an object exposed to direct sunlight, with the shadow thrown on a white background, and yet they appear soft and harmonious. Others are taken in the studio, but with a white background; a lady in Egyptian costume taken in this way gave a very striking picture. In the case of another lady, taken at an open window, the clear atmosphere formed the white background.

The CHAIRMAN expressed the thanks of the Society to Messrs. Loescher and Petsch for having, as so often on previous occasions, brought to the notice of the Society new and interesting work, the originality of which merits imitation. On account of their very artistic appearance, the photographs excited general admiration, and were warmly praised by Herren Reichard and Schaarwachter, who believed that these pictures gave an indication that photography would soon be in a position to hold its own in rivalry with creative art.

Herr WIGHT showed a new pneumatic shutter for the camera. It consists of a long board having an opening in the centre, and made to slide up and down in grooves in front of the objective. When quite at the top it is held fast by a spring, and the lower part closes the objective. This spring being released by pneumatic pressure, the board falls, and the objective is thus closed by the upper part. The exposure lasts only so long as the time taken by the opening to pass before the objective, and this time has been calculated by Herr Wight as one-twentieth of a second. To increase the length of the exposure the grooves and board are placed in a slanting position; to shorten it, an india-rubber spring is fastened at the lower end of the board, and pulls it down, so that the opening passes over the objective in about one-fortieth of a second.

Herr REICHARD described the attempts he had made to obtain on salted paper an enlargement of an ordinary negative by means of reflected sunlight without getting an image, even after an exposure of three hours.

Herr PRUMM believed that for enlargements the negative must be very thin and transparent.

Herr SCHAARWACHTER was of the same opinion, and added that he had produced very good enlargements with such negatives on ordinary albumen or salted paper by using a solar camera in which the sunlight is thrown direct on the negative by means of a condensing lens; in this way he had enlarged a carte bust to three-quarter life-size with an exposure of five quarters of an hour. With reflected sunlight, of course, the exposure would be longer, and the enlargement could not probably be carried to any greater extent with a chance of producing a good result. Unfortunately, excellent as this process is, it can only be employed to a limited extent in a place like Berlin, where the necessary intensity and continuous direction of sunlight could not always be relied on; in winter, for example, the solar camera cannot be used at all. Another drawback is that, as experience shows, the public will only order enlargements of a negative after the required number of prints have been taken from it; but, as may be gathered from what has already been said, ordinary negatives will not answer the purpose of this process, and it is not always possible to take fresh ones. To obtain the required degree of transparency is often very difficult. Instead of common paper, Herr Schaarwachter recommends the use of Van Monckhoven's nitro-glucose paper; he observed that Wunder, of Hanover, has used such paper for solar enlargements, after silvering for only half a minute, and then drying between sheets of blotting-paper. The result is that the image does not penetrate deeply into the paper, but remains on the surface, and in consequence stands out more.

A letter was read from Herr V. SCHUMANN complaining of want of success with the gelatine emulsion process, and asking for information as to the cause thereof. His letter ran as follows:—"I operated most carefully, according to Bennett's formulae. I emulsified for seventy-two hours at a temperature of from 30° to 32° C., and washed the emulsion under a tap of filtered town-water. Before coating the plate, I take care to bring both it and the emulsion to a temperature of 30° C., when the emulsion will flow easily. Drying is rapidly effected with the help of one of Vogel's drying boxes. The negative possesses wonderful delicacy, provided the film is not injured

in developing or intensifying. I develop in a pan with pyrogallie acid (1 : 300), potassium bromide (1 : 8), and one or two drops of ammonia, according as required. So soon as the finest details appear, the gelatine begins to separate, generally at the edge of the plate; after the lapse of a couple of seconds it trills, and the image is destroyed. Washing quickly to a certain extent stops the injury from extending, but it may be quite prevented by fixing before intensifying. When the plate is intensified with pyrogallie acid and silver citrate, the whole or part of the image often separates immediately previous to its attaining the required intensity. This defect is of less frequent occurrence when the intensification is effected with mercury chloride, and afterwards with ammonia. Star-shaped spots are formed, and then soon float off, and lie loose on the surface of the glass. The clearest lights are less often attacked, and remain after washing as parts of the image. I have submitted plates coated with the same emulsion to treatment of various kinds; I have developed both with iron oxalate and with pyrogallie acid, using sometimes stronger, sometimes weaker, solutions; I have intensified, after fixing, with pyrogallie acid and silver, and also with mercury, but the same imperfection always made its appearance—sometimes in greater, sometimes in lesser, degree."

HERR WIGHT remarked that he had experienced the same defects, but had not been able to discover the real cause. They did not occur now so frequently as formerly; but he could never be sure of having entirely got rid of them. He had observed that they were more likely to make their appearance when the emulsification had been extended over a long time. Great care must be taken to clean the plates properly; he himself used ammonia, and afterwards clean cloths for that purpose, and he never employed a substratum. In developing, he used a weaker solution of pyrogallie acid (viz., 1:800) than the writer of the letter. To prevent the film from separating he varnished the edges of the plates with a solution of caoutchouc. Generally he advised that plates which showed a tendency to frilling or separating should be dipped for half-a-minute into a concentrated solution of alum, although, of course, in that case, the intensifying would proceed much more slowly. He had found the above-mentioned defects to occur much oftener with plates and emulsions prepared in hot weather; on that account he recommended that plates which it is intended to use in summer should be prepared in the cool weather of spring.

Herr O. LINDNER always uses a substratum for gelatine plates, as without it he found it difficult to obtain an even coating.

The next meeting was held on the 4th July, Professor VOGEL in the chair.

Professor SPORE informed the Association by letter that the Solar Observatory at Potsdam was now approaching completion, and stated that it would be open to members under certain conditions. The President suggested that so soon as the Institution was definitely in working order the members of the Association should undertake an excursion to visit it.

Herr METNER, of Breisach, sent an illustrated list of prices of dynamo-electric machines for the electric light. The President drew attention to one of the smaller machines, producing a light equivalent to 300 candles, which he thought might be very useful for photographic purposes. Such a machine would cost about £34, with an additional £9 for the self-regulating lamp; it is on the Siemens' principle, and requires two men to turn it.

Herr REICHARD feared that a machine set in motion by hand would produce an irregular light; it had been observed that gas-motors were open to this objection.

Professor VOGEL explained that any unsteadiness in the light was not due to the machine, provided that the fly-wheel and transmission by toothed wheel run smoothly.

Herr C. QUINDE was of opinion that for the purpose of enlarging—to which purpose the electric light would in the first instance be applied—unsteadiness would not be of any great importance.

Dr. VOGEL exhibited two examples of metal decoration, produced by Herr Falk's photographic method; one of them was a plate with figure drawings, the other a lamp-stand with ornaments. The method consists in coating the metallic surface with a photographic film, which is then exposed under a transparent positive; by this arrangement the parts lying beneath the dark places of the positive are not affected by the light, and are consequently capable of being etched.

With curved surfaces a print taken in fatty ink on paper by a photographic method is transferred to the metal, and all the parts covered with the ink are by this means protected from the etching. It is a peculiarity of this process that the etching fluid colours all the etched places black, and this adds considerably to the effect of the whole.

Herr SCHAHL showed some specimens of prints taken by a new process. His method, as he described it, is to coat a thin zinc plate with chromated gelatine, which he then exposes under a negative. The film is then rolled up with some reducing substance, which adheres only to the parts affected by the light. Tracing-paper impregnated with iron is then pressed against the plate, and the iron being reduced at those places, an image is obtained which is said to be much more delicate than one produced by ordinary photo-lithography.

Herr BOLL reported the results of an experiment to sensitise albumenized paper by direct immersion in the silver bath, instead of floating. He found that when the silvering was executed in this way for about four minutes, the paper copied about one-third more rapidly than one silvered only on one side, and that the pictures obtained left nothing to be desired as regards purity and brilliancy.

Herr BRANDT remarked that this method used formerly to be recommended in cases where the bath was weak; but Herr Boll objected that with a weak bath the albumen was liable to separate.

Herr MAROWSKY pointed out that when a little silver is accidentally deposited on the reversed side of the paper the spot becomes visible in copying, but disappears again in fixing. Occasionally such a spot appears lighter than the rest of the picture.

Referring to this, Herr HALWAS had observed that spots of a similar kind only make their appearance when the bath is weak.

Professor VOGEL explained the greater sensitiveness of paper silvered on both sides by the fact that a portion of the metallic chloride with which the paper is impregnated is not reduced when the paper is silvered on one side only, and affects the sensitiveness.

Apropos of this discussion, Herr RICHTER mentioned that he had detected no difference between papers silvered for three minutes only, and those left in the bath for half-an-hour; when, however, the length of this operation is reduced below the former time—say from one to one and a-half minutes—the paper will be found to be appreciably less sensitive, and to copy much harder.

At the conclusion of the meeting it was resolved to adjourn for the holidays; consequently the next meeting will be held on the 19th September.

Talk in the Studio.

A LEICESTER MANUFACTURE.—Very few people, excepting those in the trade, know from whence comes most of the English prepared paper for photographic purposes. Leicester supplies very large quantities, and many of the largest firms in the Kingdom are supplied by Messrs. Meadows and Son, of Hum-borston Gate, Leicester. No less than 5,000 eggs pass through the hands of those engaged, the whites only being utilised; and the enormous number of yolks are more than sufficient to supply Messrs. Dent's manufactory at Worcester, the yolks being in great demand for glove purposes. There is a demand for the yolks in Leicester for confectionery purposes; but the supply is more than being consumed, many being thrown away daily. Every sheet has to be bathed singly, and each pressed before the ream is allowed to pass out of the hands of the manufacturers. There are all kinds of tints; and the senior member of the firm being a practical chemist, and one of the best known among the members of the Pharmaceutical Society, brings his scientific knowledge to bear. It may not be uninteresting to know that a first-class hand—females only being employed, owing to their tender manipulation—can earn as much as 36s. a week; many can earn 20s., and even half-timers can receive weekly as much as 8s., and this without having the disadvantage of being in badly-ventilated premises. It is a trade which ought to be largely encouraged, considering the kindly manner in which the employers deal with their hands.

SUNSHINE.—At the Royal Observatory, Greenwich, last week, the duration of registered bright sunshine in the week was 21·8 hours, the sun being above the horizon during 90·4 hours.

FOUR HOURS IN THE DARK.—It is a humiliating confession to make—but geography is pitiless, and our national vain-glory must bow to its decrees—that for four hours in every twenty-four the entire territory of the United States is deprived of sunshine. As the sun goes down on our farthest Aleutian island, its morning rays are just lighting up the hill-tops of the western coast of Ireland, and the breadth of the Atlantic lies between us and daylight. To our Fenian citizens this may be another and cogent reason for annexing the dear little isle of the harp and the shamrock; but until it is done the exultant cry of the *Rocky Mountain Presbyterian*, that the sun never sets on the United States, must be admitted to be a trifle exaggerated. It does set every day, and, paradoxically, four hours before it rises. In the depth of our humiliation we may possibly console ourselves with the reflection that—though our British cousins can say with truth what we cannot—the sun really shines on the United States when it is up. We have to submit to four hours of sunlessness a day: England is lucky to get four hours of sunshine. So life has its compensations, and existence in the United States remains endurable, though we do not (geographically speaking) make quite so great a spread as we thought.—*Scientific American*.

ACTION OF LIGHT UPON BATTERIES.—II. *Pollat*.—A Daniell element whose copper is very clean is quite insensible to light. It is not the same if the copper is modified by oxidation or by the formation of a salt on its surface. Two Daniell elements were prepared as standards of electromotive force, the sulphates being contained in two concentric glass vessels. These elements, perfectly transparent, were kept for five months; the zinc was not affected, but the copper became coated with verdigris. Nevertheless, the elements retained their original force when the measurement was effected in the shade, but on exposure to the sun it was diminished by one-fortieth of its value. This variation ceased when the sun's rays were intercepted by a screen. This phenomenon is not due to a rise of heat, for the immersion of the battery in water at 50° produced no sensible effect, and a red glass which transmitted half the solar thermic radiations acted like an opaque screen. The luminous action renders the copper less positive.—*Chemical News*.

A NEW FLUORESCENT BODY.—According to the *Journal of the Chemical Society*, C. O. Harz has discovered a new fluorescent body in *spergulin*. This product occurs in the seed-coverings of the caryophyllaceous plants, *Spergula vulgaris* and *S. maxima* (Anglic "Spurrey"). It is produced at the time when the seeds blacken and are nearly ripe. *Spergulin* is very soluble in absolute and aqueous alcohol. Viewed by transmitted light the solution appears nearly colourless, with a shade of olive-green; by reflected light it exhibits a dark-blue fluorescence. It has not yet been obtained in the form of crystals. It is very soluble in methyl alcohol, less so in anilic alcohol, and scarcely soluble in ether or petroleum. Concentrated sulphuric acid dissolves it, forming a dark-blue liquid. The fluorescence of an alcoholic solution of *spergulin* is maintained for more than a year if the liquid be kept in darkness, but is rapidly destroyed by the action of direct sun-light, and more slowly by that of diffused light. Small quantities of caustic alkalis, or alkaline carbonates, added to an alcoholic solution of *spergulin*, transform it into an emerald-green fluorescent body; and basic lead acetate produces a precipitate. The new compound contains 61·85 per cent. of carbon, 7·05 of hydrogen, and 31·8 of oxygen. It appears to be related to chlorophyll, and is probably closely allied to phyllocyanin. An alcoholic solution of the product showed strong absorption, almost entirely in the violet; and in this respect differs considerably from chlorophyll, phyllocyanin, and phylloxanthin. Mr. Harz is disposed to regard *spergulin* as a feeble acid, the acid salts of which, as well as the acid itself, exhibit blue fluorescence, the neutral salts exhibit green fluorescence, and the basic salts are destitute of fluorescent properties.

SANDTNER'S PAPER NEGATIVE PLATES.—Common glass plates are mounted with a tissue paper, so prepared on one side for the purpose that the paper adheres air and water-tight to the plates. At first sight the glass plate has the appearance of ground glass. The paper pasted on the glass forms the support for the collodion, upon which the picture is taken by the regular wet process without change. As soon as the picture, negative, or positive, is done, the paper is cut on the outside and the negative taken off.—*Anthony's Bulletin*.

CATCHING THE "EXPRESSION."—"A little too much repose about the mouth for it to be natural," was the remark of a husband to a photographer who had taken his wife's photograph.

To Correspondents.

- S. V.—The principle of the chromograph is not patented, and we are not aware of any modifications or of any appliances which are the subject of patents. It is not a photographic process, although allied to and springing out of the process of photocollography. See our last YEAR-BOOK.
- B. C. D.—Your suggestion to make the inside of the camera white, as a means of reducing exposure, is not new; it was made very many years, and was at that time, when the notion of using diffused light as an accelerator had not been discussed, much derided, the practice at that time being to exclude every ray of light, except those forming the image, most carefully from the plate. We think the plan of exposing the plate to a low light, either before or after exposure, a better means of using light as an accelerator, than the plan of whitening the inside of the camera, as the former method is most under control.
- M. L.—An evenly diffused light all round the sitter is certainly not the best light for pictorial purposes, and if you observe a little, we think you will soon discover that you are in error in supposing it to be the most natural light, or that in which we usually see our friends. Ordinary sitting rooms lighted with windows illuminate the inmates by a side light, one side being fully illuminated and the other in shadow, except so far as it is illuminated by various reflected lights from the walls or furniture of the room. A high side-light is one of the most usual and natural lights, as well as the most effective you can use.
- B. G.—The plan of showing the negative to the sitter is often troublesome, because many good negatives cannot be seen well by reflected light. If it be imperative to show the negative, and it be so fully exposed as to show no positive image, apply a solution of chloride of gold, about one grain to an ounce of water, and watch the image at the back of the glass. It will gradually assume a positive appearance; then wash at once, and show it. In this stage it looks well, and gives a good idea of the likeness.
- X. Y. Z.—We have never seen blisters in slightly albumenized paper, only on very highly albumenized samples. It is not, however, a necessary attendant upon highly albumenized paper. It requires care that the albumen shall be coagulated right through the substance of the film. Long floating on the silver bath will effect this; floating the paper, prior to exciting, on hydrochloric acid for a second, back downwards, is said to answer; immersing the print in strong alcohol will effect it; adding alcohol to the hypo bath is said to be efficient in preventing blisters.
- TROUBLED.**—The spots on your prints are caused by the particles of bronze powder used in the so-called gold printing at the back. We have warned photographers many scores of times against the use of such cards, but some persist in the pernicious practice.
- ONE WILLING TO TRY.**—Opinions amongst experts differ as to the relative advantages of alkaline development, and iron, for emulsion plates. Certainly, the best gelatine negatives we have seen have been developed by alkaline pyro. You need not trouble yourself about the prejudice to which you confess, as the alkaline method of development was not first discovered by the person you name. The controversy is not worth reviving. But our pages contain the record which leaves the question beyond a doubt.
- B.—The white metal used for gas pipes is not to be trusted for a still. The worm should be of copper.
- J. C.—See a letter on another page.
- CHROMOPHILES.**—So far as we know, anything which would dissolve the coagulated albumen in the whites would dissolve it equally in the darks, holding the reduced silver salt forming the picture.
- Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE EMPLOYMENT OF PHOTOGRAPHY BY LIGHTHOUSES.—
THE LATE DR. SCHULZ-SELLACK—DICHROMIC VISION, OR
COLOUR-BLINDNESS.

The Employment of Photography by Lighthouses.—In France they have a photographic establishment attached to the lighthouse department, or *Service des Phares*, and we remember, at one of the Paris exhibitions, seeing a number of interesting applications that were made of photography by the establishment in question. We were reminded of the subject the other day in a walk taken to Cape Wrath lighthouse, where photographic sketches were exhibited of the proper size that a lighthouse flame should assume when it is in proper order. The Argand lamp was in use in the lighthouse, as many as twenty, hung around an apparatus that revolved, constituting the beacon; and the keepers were instructed to trim their lamps so that the flame should coincide in shape and size to the photographs hung up for their guidance. We have no doubt other lighthouses, besides the one at Cape Wrath, have similar photographic records, so that any of our readers who may feel interested in the subject need not go all the way to the very north-western point of Scotland. At the same time, if they do, there is much they will find on the way to admire. It is the first holiday tour for many years that we have not carried a small camera and plates with us, and, in the end, the weather proved so uncertain—to pass a mild remark upon it—that we were not sorry to have foregone the occupation of photographing for once. At the same time, there are some magnificent pictures to be made in the far north of Scotland. The big masses of red granite about Cape Wrath itself; the wild, rocky headland of Farrid Head; the lovely Loch Eribol, from the head of which and from the western shore rises a huge range of lofty peaks; the view from the north of the coast land that stretches south; the silvery grey cliffs that border every bay and inlet, like bright filigree edging the green sea; the coralled lochs, margined by brown sea-weed; the green-shored lake Assynt and rare Loch Maree. If one only had fine weather every day, what a paradise those north-west Highlands would be! And if—there always are ifs, unfortunately—fishermen would not turn the little inns, where they are to be found, into boarding houses, and thus leave the ordinary traveller to make shift elsewhere. Perhaps the most comfortable of resting places within a hundred miles of Cape Wrath is Cape Wrath lighthouse itself, where the keepers are well looked after in house and home by the Commissioners of Northern Lights. We have to thank the head keeper and his wife for hospitable shelter and hospitable treatment during a storm that threatened at intervals to blow us, weighted as we were with a full knapsack, in the direction of the Arctic ocean. It was not even safe in the lantern, it seemed to us, and here our good friend showed us all the secrets of his craft. There was no dioptric lens, such as are employed in first-class lighthouses—and, we believe, also, by Mr. Vander Weyde in his electric light studio—but simple Argand lamps, with reflectors behind them. These reflectors were wonderful to behold; they were huge screens of solid silver, polished *à merveille*, with a four-inch focus. Each reflector was valued at £40, and as there were twenty lights, silver to the value of nearly a thousand pounds was to be found at Cape Wrath. Petroleum was burnt, and the light shed was sufficiently luminous to pierce the gloom over the sea for a distance of twenty miles. But the brilliancy of the light depends in great measure upon the accuracy with which the flames are set—that is to say, upon making each lamp do its utmost without smoking—and as a guide to this, the photographs of lamp flames, showing exact size and shape, with which the keeper is provided, prove exceedingly useful. In the photographic establishment in France the sensitive plate

is employed frequently to test the photometric value of certain lights; but, we believe, the Trinity House in this country do not avail themselves of any test of this kind.

The late Dr. Schulz-Sellack.—We sincerely regret to hear of the death of Dr. Schulz-Sellack, which Dr. Vogel announced in our columns last week. The number of practical chemists that occupy themselves with photographic matters is already so limited that the loss of one of them is keenly felt. Although but a youthful chemist, Dr. Schulz-Sellack had made considerable study of the theory and practice of photography, and both prior to his departure to America and subsequently, the young German chemist contributed notes of considerable importance. It is painful to find that so much talent and industry were employed by its owner with such lack of success. Here we have a clever chemist compelled to assist in a New York studio in retouching negatives, in order to gain a livelihood. Even in this capacity he appears to have failed, for soon afterwards we find him in the Argentine Republic, whither he proceeded to seek his fortune. A year afterwards he returned to Berlin, as poor, evidently, as when he left the Fatherland, and tried once more to get a living out of science. But all in vain, and apparently he and his family drifted from bad to worse until, in a fit of despondency, his adopted father and mother, with himself, agreed to put an end to their struggles by suicide. It was truly a fight for life, in which humanity was worsted. Three or four years ago the readers of this journal were tolerably familiar with his name, for the communications of Dr. Schulz-Sellack were always worthy of translation. The last paper communicated, if we remember rightly, was on the subject of securing a more rapidly printing silver paper, and this the worthy doctor succeeded in doing by employing iodide in connection with chloride. But the paper was never manufactured commercially in this country, and hence little good came of the suggestion. We shall sadly miss Dr. Schulz-Sellack from the slender line of photo. chemists.

Dichromic Vision, or Colour-Blindness.—Colour-blindness, as it is called, or the incapacity to distinguish one colour from another, is again exciting attention through the publication of a work on the subject by Dr. Jeffries, of the United States, which book has been ably criticised by Mr. William Pole. Most authorities would seem to be agreed on the subject that colour-blindness (so-called) is due to a person being incapable of appreciating two out of the three cardinal colours; they enjoy only dichromic vision. Generally, in these cases, they cannot appreciate red, and thus only see violet or green. One cannot help thinking that there is in the human eye a qualitative appreciation, such as that possessed by sensitive films. We have some photographic films, for instance, which appreciate highly the red end of the spectrum, and others, again, which are acted upon but very slightly by the least refrangible rays. Since the appreciation of light by the eye is, in the main, due to a substance called visual purple, which lines the membrane of the eye, and acts in every respect like a photographic plate, this view seems to be strongly supported. In this case there would be a parallel between the eye and a sensitive film, for we have it on Dr. Jeffries' authority that some colour-blind people can appreciate red, but fail to distinguish one of the two other colours. Everybody, apparently, whether colour-blind or not, sees a distinction between the various colours, but that distinction is not recorded on the retina in every case in the same way, and for this reason, no doubt, it is that, although a great deal has been talked about the liability to accident on railways that is engendered by the employment of colour-blind engine-drivers, it is no less a fact that there never has been recorded an accident due to a man mistaking the red light for a green one. Dichromic vision, or colour-blindness, is more inherent to men than women; one man in every twenty-five has dichromic vision, while in the case of girls and women the defect amounts only to 0.2 per cent.

PHOTOGRAPHY AND THE SUN'S SURROUNDINGS.*

OBSERVATIONS during the eclipse of July, 1878, considered in connection with recently acquired knowledge respecting meteor systems, open before us a new and very interesting page of the book of nature. It remains still to be read, and many years will be required for its thorough study, but even now we can recognize the general character of its contents. We refer to the recognition by Professors Newcomb and Langley of an extension of faint luminosity to a distance of about 6 deg. on either side of the sun. Other observers also recognized either as great an extension of coronal luminosity, or such peculiarities of shape in the luminous region around the sun as show that under slightly more favourable conditions they would have seen all that Newcomb and Langley saw.

It may be well now, when the attention of astronomers has been directed afresh to meteoric systems, to re-examine the important series of observations made during the last eclipse.

Hitherto in eclipse observations no luminous appearances have been satisfactorily recognized at a greater distance from the sun than perhaps about two of his own diameters, or some $1\frac{1}{2}$ million of miles. Unquestionably rays have been traced to a greater distance which could not possibly be regarded as other than solar appendages, including under that name all phenomena, whether coronal, zodiacal, cometic, or meteoric, which have relation to the sun, as distinguished from luminous appearances having their origin in regions not farther away than the moon. Any long ray extending from the eclipsed sun and visible in a constant position during totality must of necessity be due to a solar appendage. Such rays have been indeed referred to matter nearer than the moon; and as our own air most certainly could not explain them (for not a particle of our own air within 6 or 7 deg. of the eclipsed sun is in sunlight at mid-totally), scattered particles of matter travelling between the earth and the moon have been imagined in explanation of these long rays. An ingenious experiment was devised in illustration of this theory. If an irregular plug be inserted into a round hole (or a round plug into an irregular hole) in the shutter of a darkened room in such sort that the sun's light enters the room through the interstices, appearances very much resembling those long rays will be seen where the solar rays fall on the dust-laden air of the room. In this experiment the plug represents the moon, the sun is himself (as Launce would have said), and the air in the room represents the cis-lunar matter of the theory. But those who have adopted the theory and accepted this ingenious illustration appear not to have observed a trifling distinction between the circumstances of an eclipse and those of the suggested illustration. The shutter is a rather necessary adjunct to the experiment. If the sun's rays only pass in through small interstices to illuminate the air in the room, the radiating streaks are observed; but if they fall freely into the room (save where a small opaque disc is suspended in the window, to represent the moon), no such rays can be seen. Now in the eclipsed the plug is represented well enough by the moon; but the shutter is omitted. The omission is somewhat important. To say the truth, no one (certainly no mathematician) who takes fully into account the actual circumstances of a total eclipse of the sun can fail to perceive that a long ray seen in an unchanged position during the whole continuance of total eclipse must certainly belong to regions far beyond the body of the moon. Now since such rays have been seen on several occasions, we have in one sense satisfactory evidence of the existence of solar appendages outside the corona. But it has been held that until such rays have been seen and identified by at least two observers on the same occasion, they must not be treated as scientific realities, however certain the individual observers of such

features may have been that their descriptions were exact. It had so happened that evidence of this kind had not hitherto been obtained. Different observers had seen long rays on the same occasion; but their accounts differed widely. Often, indeed, it seemed impossible to believe that the same rays had been observed. From what we have since learned, however, respecting the corona itself, we perceive that in the excitement of an eclipse observers are capable of the wildest errors of description and delineation. Until "the retina which never forgets" had viewed the corona, it was objected that an object which different observers saw under entirely different aspects could not possibly be a real solar appendage; but photography has shown that the discrepancies were due to inexact observation. They were found to have no existence in the corona itself as photographed from widely separated stations. If photographs of the long rays could have been obtained, the discrepancies in their case would doubtless have been removed in like manner. But, unfortunately, the lustre of these long rays is exceedingly faint, and hitherto they have not been shown in any photograph of an eclipse. Hereafter greater success may be obtained in this direction, possibly by doing what was strongly urged long before the late eclipse—devoting, namely, the whole duration of totality to obtain one really effective photograph. There is no longer the slightest advantage to be obtained from taking several photographs, for the doubt which formerly rendered that course necessary (the suspicion that the corona changes during totality) is no longer entertained. For the present, however, we have only drawings or descriptions to deal with. It is the distinctive feature of the observations made in July, 1878, that these drawings and descriptions show most satisfactory accordance. We propose to consider a few of them, taking first those which give to the rays or luminous projections their least extension.

In the first place, we take a drawing of Mr. J. N. Lockyer. In this drawing the black body of the moon is shown surrounded by a narrow ring of light, the inner corona. Outside the ring are three projections, nearly in the ecliptic. (It is important to notice this, for the axis of the zodiacal light is at all times nearly in the ecliptic.) On the eastern side there is one projection, shaped like a long isosceles triangle, the base of which is on the moon's edge. On the western side are two nearly equal projections, bearing somewhat the same relation to the single eastern one that the two sides of the tail of a wind-vane bear to the pointed head. The three projections are not very unequal in length, the longest extending about $1\frac{1}{2}$ diameter, or about 2-3ds of a degree, from the sun's edge. This would correspond to rather more than 1,000,000 miles. The resemblance to a wind-vane, says Mr. Lockyer, "was almost perfect (the corona), being pointed at one end, and bounded by parallel edges at the other;" "others," he adds, "saw a resemblance to a fish's tail." The breadth of the wind-vane in his picture is about 3-4ths of the sun's diameter. It is worthy of notice that in the telescope the streamers vanished utterly. "Not a shred of them was left." This shows the extreme faintness of their light; the slight absorption of light by the glass of the telescope (a $3\frac{1}{2}$ -inch Cooke) sufficed entirely to obliterate these delicate solar appendages.

General Myer, the head of the Army Signal Service, and commonly known in America as "Old Probabilities," because the weather forecasts daily published appear under that heading (without the adjective), saw the corona from the summit of Pike's Peak, 14,200ft. above the sea level. He described the corona as showing five radial lines of a golden colour, beyond which in the direction of the ecliptic "were prolonged bright silver rays." This was seen only with the naked eye. "In the telescope the appearance was quite different; a layer close to the sun only, of a light pink colour, was seen; the long bright silver rays had disappeared." It is worthy of notice that General Myer had

* *The Times.*

on a former occasion seen the long coronal rays in circumstances almost as favourable. He watched the progress of the eclipse of 1869 from the summit of White Top Mountain, near Abington, Virginia, 5,530ft. above the sea-level. On that occasion he saw in the telescope only an aureola of clear, yellowish, bright light, closely surrounding the moon's disc, and fading gradually into the tint of the darkened sky, "with a slight tinge of pinkish green" (a colour almost as difficult to imagine as the "gris rouge" mentioned in Molière's *L'Avare*). But to the unaided eye the eclipse presented "a vision magnificent beyond description." Around the full and intensely black disc of the moon there was an aureola of a soft bright light, "through which shot out, as if from the circumference of the moon, straight, massive, silvery rays, seeming distinct and separate from each other, to a distance of two or three diameters of the lunar disc, the whole spectacle showing as upon a background of diffused rose-coloured light." It is specially interesting to note the arrangement of the long rays on that occasion. For the eclipse of 1869 occurred on the 7th of August, the time of central eclipse for the whole earth being 9h. 46m. p.m. Greenwich time; and the eclipse of 1878 happened on the 29th of July, the time of central eclipse being 6h. 23m. p.m. Greenwich time; so that the two eclipses occurred at the same time of the year within nine days 23 minutes. The actual directions in which the observers of the two eclipses looked at the sun were inclined to each other in an angle of less than 9 deg. So that, in point of fact, we may say that very nearly the same view was obtained of the sun's surroundings on both occasions, apart from any changes which may have occurred in the interval. If it should appear that the long rays presented the same general aspect in 1869 as they did in July, 1878, then the inference would be that they are objects not changing as the sierra, the prominences, and the inner corona change. We could not safely conclude that this is the case; but it would be the most probable inference. Now, General Myer, in 1869, said that the silvery rays were longest and most prominent at four points of the circumference, two upon the upper and two upon the lower, portion, apparently equidistant from each other, giving the spectacle a quadrilateral shape. The angles of the quadrangle were about opposite the north-eastern, north-western, south-eastern, and south-western points of the disc. The description is not exact, but it accords well with the conclusion that two of the rays (north-eastern and south-western) were in the ecliptic, and the other two at right angles to the ecliptic. If so, there seems good reason, as will now appear, for believing that the rays seen by Myer in 1869 may be the same, or, rather, belong to the same cosmical appendage of the sun as those seen by him and by other observers in July, 1878.

(To be continued.)

THE TIMES ON AUTOTYPES.*

"IN Mr. Elmore's work, as already mentioned, the monochrome was entirely painted by the artist himself; and the whole system of autotype reproduction is open to the objection that much very valuable time must in this way be consumed. Even from a commercial point of view, however, such time is by no means thrown away; since the monochrome itself, in proportion to its size and finish and to the reputation of the artist, possesses a money value which in many cases might adequately repay the labour incidental to its production. Again, there will be instances in which the painting of the monochrome may be only partly done by the artist himself, and partly under his direction; and an illustration of this is furnished by the reproduction of Mr. Poynter's painting, 'Israel in Egypt,' which was exhibited at the Royal Academy in 1867, and which, in the same summer, furnished Mr. Tenniel with the subject of one of

the best remembered cartoons in *Punch*. This painting was purchased by Sir John Hawkshaw, who for a long while retained it for his private gratification, and refused to send it to any of the various private loan exhibitions which from time to time were set on foot. He was, however, induced to allow it to go to the Exhibition last year at Paris, where it held a conspicuous place among the examples of British art. As most people will remember, it was a picture of many figures, clear sky, intense light, and vivid colouring; and by direct photography it would have been impossible to obtain a reproduction of it which the artist could have accepted. By the intervention of a monochrome, such a reproduction has been obtained with conspicuous success; and although the monochrome was not entirely painted by Mr. Poynter, he has worked himself upon the whole of the figures, and has supervised and certified to the rest. The result is a very striking and accurate record of a work of art of a high order of excellence.

"A less successful example, and one which shows that the mind, at least, if not the hand, of the artist must be given to the work, is furnished by the 'Royal Garden Party at Chiswick' of M. Desanges. The autotype of this picture would, nevertheless, elicit commendation if we had not better specimens of the method before us; and it is said that, although the monochrome was revised and touched by M. Desanges, he was not able to devote to it the time and care which were required for the thoroughly effective rendering into black and white of the numerous portraits and the brilliant and varied colouring which were contained in the groups of persons represented. The result does not in any way tell against the process employed, but merely serves to emphasize the necessity for the employment of adequate care and skill in one of the most essential of the steps by which the desired effect is to be brought about.

"Where the autotype is employed for the reproduction of originals in black and white, whether these are in charcoal, grisaille, chalk, pencil, ink, or any other medium, the copies imitate the originals so closely that very careful inspection would be required in order to distinguish between them. Of such copies, a very large number by various artists have now been published, and they bring correct and finished studies of nature within the reach of all classes of the community.

"Besides the works of the moderns, the Autotype Company has also published a large number of copies of drawings by old masters, such as those in the Sistine Chapel; and these, many of which are of considerable size, while all are extremely moderate in price, lend themselves admirably to many purposes of decoration. We have seen walls almost papered with them, the subjects being carefully selected with a view to harmony of general effect, and the pictures separated only by slight beadings. In some instances they might no doubt be sized and varnished so as to require no glazing, and to admit of being cleansed from dust without sustaining injury in the process.

"In these days of general art cultivation, when so much is being done, and on the whole with so much success, to spread abroad a love for the beautiful among all classes, the combination of scientific manipulation and commercial enterprise displayed by the Autotype Company deserves hearty recognition as a most important aid in the good work. That it is a good work we need not now stay to argue, for the position will be generally admitted; and we think it must also be admitted that pictorial art, as that which is more readily appreciated by the comparatively untaught than any other, is entitled to claim the first place as a means of elevating the tastes and quickening the perceptions of the bulk of the community. It is worthy of the consideration of those concerned in education whether they might not do something to render the work of the Autotype Company more widely known—whether, for example, it might not be possible to give well-selected pictures as prizes in Board and other schools, and to carry out on a wider and more extensive scale what is done by the Art Union for works of a different and

* Continued from p. 446.

in some cases of an inferior class. In Manchester there is an 'English Picture Publishing Company,' which issues to its subscribers single works, or sets of works, as the case may be, for a guinea, a guinea and a half, and two guineas; and for this Company the Autotype Company has already produced paintings by F. M. Brown, C. W. Cope, R.A., F. J. Shields, William Blake, Wallis, and Rossetti, besides having others by Rossetti, Burne-Jones, and other artists in preparation. The distinguishing character of the Autotype reproductions is that they are cheap and absolutely faithful copies of originals, which may themselves be of the very highest excellence; and they are therefore especially adapted for all situations in which the moderation of their cost is an important element, and especially for all in which it is desirable, for educational reasons, to keep before the eyes, either of children or of adults, the most perfect representations of natural or of ideal beauty."

SO-CALLED SPIRIT PHOTOGRAPHS.

THE *Rochester Union* is puzzled by the claims of "Spirit Photography." It says:—"It may not be generally known that for the past two years spirit photographs have been taken in this city, some of them being certainly extraordinary productions. The power granted by the inhabitants of the unseen world to reproduce their features on a camera is not given to every one, and in this section, so far, Miss Hedley, who runs a photograph gallery on State Street, has a monopoly of what is likely to turn out a most lucrative business. Hearing of Miss Hedley's gift in this line, a citizen, being of a curious turn of mind, determined to see what there was of it. Visiting the gallery, he told the proprietress that he understood she took spirit photographs, and he wished to test her skill.

"I am not certain I can succeed," was Miss Hedley's response. "but we can try."

"Would you allow me to pass my handkerchief over the glass before you prepare it for the camera?"

"Oh, certainly, as many times as you wish."

The visitor carefully rubbed the glass on both sides, after which he stood while the collodion was put on, and when the glass was put in the camera he took his seat. The cap of the instrument was removed, and in a few minutes the picture was taken. On the negative being taken out and held up to the light, some faint forms around his chair was visible.

"What are those marks on the glass?" asked the citizen.

"Those are faces of some persons you will no doubt recognize when printed plain."

"Well, when can I obtain a proof of the picture?"

"Oh, by to-morrow."

"No; I intend to have a proof while I wait, as I do not intend there shall be any humbug in this matter."

"After waiting about two hours the proof was taken, toned, and placed on a card. It was then that he recognized in the most distinct manner the faces of his sister and child, who had died some time previous. Not wishing to be made the victim of an optical delusion, he put the card in his pocket, and on going home, showed it to his wife, without saying a word. She immediately recognized the faces on the print, and her husband then told her how it was taken. It was shown to friends of the family, who also recognized them."

DOUBLE ALBUMENIZED PAPER.

THE Editor of *Anthony's Bulletin*, referring to the use of double albumenized paper, has some good hints on blisters. He says:

"Having received from one of our customers some of the Dresden paper which was complained of as blistering badly, we sent some sheets to the manufacturer, who returned some prints made upon it perfect in every respect. In order to provide our customers with everything necessary for success in using this paper, we at once wrote to the manufacturer for the formula or mode of working. This will be found below. It will be observed that while

they do not prescribe a silver bath as strong as is generally used in this country, they nevertheless do not fume the paper, nor do they use the acid wash before toning.

"INSTRUCTIONS.

"*Silver Bath*.—40 grains to the ounce of distilled water. Filter the bath always before using it, and stir it after each sheet has been floated. Float one to two minutes.

"*Toning Bath*.

No. 1.—Acetate of soda	60 grains
Distilled water...	1 quart
No. 2.—Pulverized borax	45 grains
Distilled water...	1 quart

Mix equal parts of these two solutions an hour before using, and to every 2 ounces of this mixture add 1 grain of chloride of gold, dissolved beforehand in a little distilled water.

"*Fixing Bath*.

Hypo-sulphite of soda	3 ounces
Ordinary drinking water	3 pints
Time of fixing	15 minutes

"The temperature of all the baths must be uniform. Silvered papers and finished copies must not be dried quickly. Mount the copies while wet.

"In case after using the above baths the copies show show blisters, the mode of obviation is as follows:—

"*Unfailing Means for Preventing Blistering with our Double Albumenized Paper*.—The copies after leaving the toning bath must be washed several times with pure water, and then placed one by one in a solution made by adding to one quart of water one drachm of pure muriatic acid. In this bath the prints are to soak from two to three minutes, being kept constantly in motion, and afterwards they are to be washed again from two to four minutes in pure water to free partially from the muriatic acid. On hot days this washing must be continued longer than on cool days. After this the prints are to be put in the fixing bath. Should the prints after fixing show a yellowish tint (which, however, will scarcely ever occur), this can be prevented by passing the prints quickly, after being drained of the excess of muriatic acid wash, through a solution of water and ammonia, $1\frac{1}{2}$ drachms of ammonia to one quart of water; then rinse in water, and place at once in the fixing bath. By this means any alteration of tone is prevented."

A RAPID PROCESS FOR DIRECT PRINTING AND ENLARGEMENTS.

BY LEIGHTON PINE.*

PLACE in a half-gallon bottle an ounce of nitro-glucose, and pour over it two ounces of sulphuric ether. When the glucose is dissolved, add to it an ounce of chloride of ammonium dissolved in as little water as possible, with sufficient strong alcohol afterwards added to make in all forty-eight ounces of solution. The addition of forty-eight grains of citric acid to the above mixture completes the preparation of the salting solution, which is applied to the paper by means of a brush, the operation being quickly performed. When dry, the paper will keep ready for exciting, for several months.

Paper thus salted may be employed either for direct printing in the pressure frame, or for developed enlargements.

For ordinary printing the paper should be floated for about a minute on a sixty-grain silver bath. When dry it is exposed to the fumes of ammonia for about fifteen minutes, and then exposed under the negative.

The author of the process says that with paper so prepared he has obtained from a clear intense negative, in sunshine, a print in half-a-minute. "It was clear, round, and brilliant, and the details were wonderfully soft and deep. Altogether it was just the kind of print operators strive to make, and, when made, feel justly proud of their success." The sensitiveness implied in the above must strike one as being indeed very great. The toning and fixing are effected as usual.

When the paper is intended for developed enlargements

* *St. Louis Practical Photographer.*

a greater degree of vigour and roundness is obtained if the quantity of citric acid in the glucose salting solution be doubled. It is excited by floating it upon a forty-grain silver bath, which before and after using should be placed in the sun, in order to cause the organic matter to be deposited.

The exposure is continued until the image be faintly visible, and the print is developed by the following—

Pyrogallic acid	1 grain
Citric acid	1 "
Water	1 ounce

If the exposure has been properly timed, the development of the print will be completed in little over a minute, after which it is washed, toned, and fixed by the usual means.

METHOD OF OBTAINING PURE WHITES IN FERROTYPES.

A WRITER in the *St. Louis Practical Photographer* says:

"Ferrotypes do not always exhibit the pure silvery white that operators desire, the colour being often ashy or ochrous, to the great detriment of the picture. In some experiments we have obtained proofs which appeared more brilliant than most of those generally seen. Our process, however, can boast of nothing new; it consists in the addition of a certain quantity of sulphuric acid to the iron developer, which enters into a host of formulæ already given; and if we have had better results, it is due to our employing, instead of an empirical formula, one based upon the elementary laws of chemistry.

"To obtain a brilliant metallic white, it is necessary that the molecules of silver, which are deposited and form the image, should be as pure as possible; we must, therefore, inquire what takes place when we develop a picture.

"The oxide of silver in the nitrate is decomposed by the sulphate of the protoxide of iron, and while the silver is reduced to the metallic state, the sulphate of the protoxide passes to the state of sulphate of peroxide. But the sulphate of the peroxide of iron thus formed is basic and insoluble; it envelopes, as it were, the molecules of silver deposited at the same time with it, and communicates to the silver an ochrous tint. Instead of the insoluble basic peroxide of iron we ought to obtain the neutral sulphate, which is soluble in water; but this is formed only when we add to the iron solution a certain quantity of sulphuric acid.

"In practice, and to have round numbers, we may say in general terms that the quantity of sulphuric acid must be equal to one-fourth of the sulphate of protoxide of iron.

"The following formula may be given:

Water	12 ounces
Alcohol	5 "
Acetic acid	6 "
Sulphate of protoxide of iron in crystals	4 "
Sulphuric acid (by weight)	1 ounce
" " (by measure)	5 to 8 ounces

THE WAY TO PHOTOGRAPH CHILDREN.

BY S. L. PLATT*

Too little attention is paid to this branch of business. The artist is usually very busy when the child is brought, and arises at the squall of the child, and begins to scratch his head, then, after a heavy sigh, starts for some old cubby-hole, hands out the remains of a chair resembling the one used by Adam in his infancy. The mother looks at the chair with a hudder, and claps her hand over the child's mouth: the artist goes for a duster, and an old coat for a covering. After the chair is dusted and covered the best he can, he seeks some branch of amusement by the way of blowing an old whistle, screaming, shaking keys, or picking the last string of some old fiddle. This, in time with the child, is music for the blind only, and to all looking on seems silly.

In order to do away with the above nonsense, take an ordi-

nary high chair, and fix the back with a stationary curtain, so it is straight, up high enough to support the child's head; pad it so the back will keep the child from moving sideways; cover with a nice spread; then focus the instrument on the back; have the baby to sit, so it will bring the glass in focus at that point. After this is done, take your position back of the chair, and as soon as the mother places the child in, fasten him with a cord; then get ready for the exposure. Don't appear to have seen the baby, and he will not be afraid. Let the mother seat herself by the side of the child, and hold her peace. Then light a torch, made by soaking a cork in oil, on the end of a wire. As soon as you see the child's attention is drawn by it, make the exposure. Never let a child know anything is required of it, but go on about your business, and it will be sure to have its eyes on you.

When a child is to be photographed, old enough to understand what you say to him, do not let him know you wish any more than to show him how pictures are made. Have him sit or stand, as you choose; then take a small mirror, three inches wide, five inches long, and hold above the tube of the instrument, and call his attention to it. Show him his picture in it, but do not look toward him; you can watch his movements in the mirror; that is what it is for. When he is still, make the exposure. He will not know he has had a picture taken, nor when.

If you look at a child of that age, and try to get his attention, he will look and appear awkward. It would be rather difficult for a grown person to sit and be stared at, and hooted at while sitting.

Now, always keep a small mirror in the gallery for this purpose, as it will be of great use to you.

FOR RETOUCHING.

BY J. C. ELROD.*

TAKE a window, one that you can use for that purpose with comfort and convenience, get your carpenter to fit nicely a board wide enough to work on the largest negative you make, but have the board wide enough to hold a 11 by 14 negative, stripped or headed on the bottom edge to keep things from slipping off; fasten the board at the proper angle, so that you may stand and the height from the floor will be such that your arms from elbow to the wrist will lie at ease in the position you wish them, so that you may stand erect and work with ease. Now cut a hole so as to admit a 4 by 4 glass set in the middle of the board, which reaches across the window, securely fastened at each end, the upper edge of the board as near the glass as the sash will allow. Now cover the board with green baize, cutting away the cloth over the 4 by 4 glass over which you are to do your retouching. Exclude all the light coming through the window above and below your retouching board, except underneath the board, right in front of the 4 by 4 glass; under the glass suspend or swing, by means of screw eyes and strings, another small board just large enough to lay a sheet of writing paper on, and so adjust the position of the under small board that when the white paper is on it, the light will reflect just where you want it when retouching. Remember no light must come in through this window, only through the light of glass under the retouching board, so as to fall on this white paper in position. You may have a stool so that you can sit or stand while retouching. Windows facing the north are best for this purpose. If you use a window facing south, east, or west, screen off the sunlight with white paper, so that the light you work by shall be soft and uniform. The light must be excluded also from your back, by curtain, screen, or otherwise, so that you see only the light passing through the negative. The retoucher may then stand or sit at will, holding his or her chest erect, thereby working with ease and comfort, doing twice as much retouching in a day, doing it better, and feeling less tired at the end of the day's work than is possible with one of those little movable retouching boards so commonly used.

TRADE UNIONISM IN PHOTOGRAPHY.

THERE have been various symptoms manifested of late years of a tendency to establish trade-unionism in photography. We have noticed indications, on the part of some, of a desire to convert the Photographers' Benevolent Society into something of the kind. We have no intention of entering into any discussion of the general principles generally cultivated in trade-unions, beyond remarking that, so far as we have had opportunity of noticing, they are generally tyrannical and unfair, destructive of personal freedom and self-respect, and the worst form of the exploded principles of protectionism. But apart from the question of right or wrong in trade unionism, we may throw out a passing warning of the danger of importing anything of the kind into the Benevolent Fund. Established entirely for the benefit of the unfortunate assistant, it is at present largely assisted by the contributions of honorary members, and nothing could be more suicidal than an attempt to use against the employers the machinery they have helped to establish.

The principles of the trade-union are, however, proposed for adoption in America in a very different manner. A contributor to the *St. Louis Practical Photographer* proposes a combination of professional photographers against the public for the maintenance of prices. Those photographers who do a cheap trade are to be ostracised, or, in familiar parlance, "sent to Coventry," by the profession generally. Nothing is more natural, perhaps, than that a high-class photographer, conducting his business in the most respectable style, should look with contempt upon, and refuse association with, the cheap-Jacks of the profession. But to form a combination to influence or control the low-priced brother will scarcely bear examination. It is an attempt to control his liberty of action. Possibly his work is only worth a low price, and he is possibly aware of it. But the greater iniquity would be if he did good work at a low price. This is the man whom the trade-unionists would especially put under control! The writer in the *Practical* is aware that the position of the protectionist is assailable, and endeavours to vindicate it. He says:—

"I believe that as the demand is to the supply, so will the price be. I think that proposition is invulnerable. But as the control of the supply is often resorted to to raise prices (the corners in the grain market, for illustration), would it not benefit our craft, without injuring the public, to raise a corner in our production by doubling the rate for cheap work? Is there an artist in St. Louis, or New York, or any other city, who has doubled his income by reducing his price one-half, say from three dollars a dozen to \$1.50 for cards? To double his income his business must increase three-fold, and who has ever done this? Now, my idea is to organize a National Photographic Alliance—call it by what name you

please—and pledge ourselves not to make a card-photo. below three dollars per dozen; not to recognize any one who does so, and not to deal with any stock-dealer or other person who will supply goods to any one who works below that rate. I would not fix that as the price, but as the lowest price. Three dollars a dozen; half-dozen, two dollars. No sitting for ferrotypes below fifty cents, nor less than twenty-five cents for a picture, no matter how many are taken.

"At first sight it seems as if this could not possibly be accomplished, and there is but one way in which it can be done. That way I have pointed out—stop the supplies. That is the secret, and that is certain. Utterly refuse to recognize any so-called artist who works below that price, and buy from no dealer who does. No fear of outsiders adding photographic goods to their stocks if only the shysters will buy from them. And if all the artists in the Union will raise their prices to the standard given, three months will see every one of them doing a better paying business than he is doing at present, and very little less in amount. No doubt stock, as well as prices, would advance, but the advance in stock would never be felt by the artist. It could not be done in a day. Some parties would refuse to join such an alliance. Some stock-dealers would supply them with goods; but if it were once generally adopted, the stock-dealers could not afford to hold out and lose their best customers; and when the cheap-Johns ran out of stock, and found that they could not replenish without a certificate of membership from the local secretary of the Alliance, there would be some tall talking, but it would end by their joining the Alliance or quitting the business.

"There is no bulldozing in this idea. Every man has an inalienable right to say, I will not deal with you except on certain conditions; or, I will not recognize you while you follow your present course. In fact, we all exercise just this right in our social habits. If we make a call and are not treated as we think we should be, we do not go back. If a person calls on us whose company we do not want, we decline to receive them, or treat them in such a manner as to prevent a repetition of their visit. Forcing a party to acquiesce with my ideas under fear of bodily harm or injury to their property is a very different thing from simply withdrawing intercourse while they continue in a given course of conduct. In the one case the man has no choice; in the other his freedom of action is not interfered with. We simply let him alone.

"The greatest good for the greatest possible number, is the basis of law in free countries.

"We try to prevent crime by the punishment of criminals. In doing so we necessarily interfere with their liberty of action when they choose to do wrong, and the good of society at large demands that this should be so. When a party deliberately injures our business by cutting down prices below living rates, we have a perfect right to use any and all legitimate means to coerce them back to a legitimate line of action. Ostracism is the only course open to us, and I, for myself, will openly urge its adoption."

The sophistry of this mode of arguing is very apparent. The writer assumes that he whose charges are too low for photographers is guilty of crime, and that it is legitimate to use coercion to regulate prices. We strongly recommend the maintenance of a thoroughly remunerative scale of prices, and would gladly see an agreement amongst respectable photographers to effect such an end; but it should be perfectly voluntary, and withholding involve no penal consequences.

Critical Notices.

LANTERN READINGS. (F. YORK, Lancaster Road, Notting Hill.)

MR. YORK must be regarded as the good genius of all the school children who are fortunate enough to be treated periodically to lantern exhibitions. Every season is inau-

gured with a new catalogue of slides, containing extensive and interesting accessions to his already enormous stock of slides; and also fresh series of Readings to give interest to sets of slides, and save the exhibitor the sometimes trying task of preparing a series of brief lectures which shall be instructive, appropriate, and interesting. Foremost among the new Readings just issued, with new and suitable slides, we find the Zulu War and Zululand are treated. The place and the people, and their habits and manners in peace and in war, are fully treated, and made interesting. Bible manners and customs is the subject of another excellent series of slides and Readings. There are varied Readings especially intended for the young, at once instructive and entertaining. The subjects are admirably selected, and the treatment in the Readings possesses a degree of freshness and interest which must make them a great boon to the exhibitor, as well as to the audiences for whom they are intended.

THE MAGAZINE OF ART, Illustrated. (London: CASSELL, PETER, AND GALPIN.)

DURING the last quarter of a century many magazines of Art have been launched to float aimlessly on the waters, and finally sunk to be forgotten. As a rule, they have possessed no character or material of a kind to interest artists, and very little to attract the educated public. In many cases they have seemed, in fact, chiefly to be intended as vehicles to use up the old plates and blocks which, having done duty before, were thought good enough, when collected together, to illustrate a magazine of art. The magazine issued from the well-known publishing house in Belle Sauvage Yard has now existed upwards of a twelvemonth, and promises to deserve and secure a better fate than its predecessors. It is well illustrated, and possesses some readable papers. A portrait of Briton Riviere, A.R.A., and copies of some of his pictures which have appeared in the Academy, will interest many. Sketches of pictures and painters of the year are interesting. A readable paper on Sketching in the Umbrian Valleys, by Stephen Thompson, is very good. There are other capital papers and illustrations, all possessing some human interest, altogether different to the fossil-like character common to the majority of art magazines which have found already a well-merited oblivion.

FRENCH CORRESPONDENCE.

VAN MONCKHOVEN'S STUDIO PHOTOMETER—MANUFACTURE ON A LARGE SCALE OF GELATINO-BROMIDE DRY PLATES—HIGHLY SENSITIVE FILMS AND RAPIDLY-MOVING SHUTTERS FOR THE OBJECTIVE—ALLEGED INFERIORITY OF FRANCE IN PHOTOGRAPHY—THE PAPHYROGRAPH—PUBLICATION OF A PRACTICAL GUIDE TO PHOTOTYPY BY THE AUTHOR.

THE summary which I have (perhaps rashly) placed at the head of this letter is a sufficiently extensive one. It will require considerable effort to be concise in order to include within the necessarily limited space at my disposal a notice of all the subjects hinted at in this summary.

A New Photometer for the Laboratory.—My friend, Dr. Van Monckhoven, always active in the cause of photographic improvements, has just sent me the description of a new instrument which can be used as a thermo-photometer. Its principle of construction is based on the action of the solar rays on uranic oxalate, converting it into the uranic salt with the disengagement of a certain quantity of gas; the latter is accumulated in the upper part of a flask containing a solution of uranic oxalate in water. In the neck of the flask is fitted an india-rubber cork, pierced by a capillary glass tube, the lower end of which is cut off flush with the under surface of the cork. The gas accumulating in the upper part of the flask produces a pressure on the solution of uranium, so that the latter rises more or

or less in the capillary tube, according as the amount of gas disengaged is greater or less, and the production of the gas is found to be proportional to the action of the light. By means of a scale engraved on or affixed to the tube the intensity of the luminous rays can be measured. As the *Bulletin de l'Association Belge de Photographie* will contain a more complete and detailed description of the invention of my ingenious friend, I shall confine myself on the present occasion to some remarks on the use of such an instrument, which will, I think, meet a great want. Every photographic studio ought to possess a light measurer, if I may so express myself, or, to use a better word, a photometer, for it is the light which is the primordiate agent in all photographic operations. The instrument invented by Dr. Van Monckhoven will, when it is perfected, answer this purpose, since it is no less a thermometer than a photometer—for the action of heat, independent of that of light, will cause dilatation on the fluid in the flask, and hence increase the size of the liquid column in the capillary tube—a correction will be found necessary, so as to establish the action of the light alone independent of that of heat. On the other hand, as there is gas given off, there must evidently be a decomposition of the uranium compound, and it is, therefore, important to know what is the cause of this decomposition, and how long without renewing it takes for a standard solution of the uranic salt to be converted into one of the lower oxide. Hence the graduation ought, as it appears to me, to be so arranged—and it can scarcely be a difficult matter—that every degree shall correspond to a certain established unit of the action of light, for instance, to the action of direct sunlight on the instrument in one second of time. I shall endeavour to follow the path indicated by Van Monckhoven, on the one hand, in repeating his experiment; and on the other hand, in effecting improvements in the instrument of the kind I have pointed out, adhering, however, closely to the principle which he has adopted for its construction. The idea is certainly an excellent one: it is only requisite to apply it in the best way in order to obtain an application at once serviceable and practical.

Manufacture of Gelatino-bromide Dry Plates.—The production and sale of these plates has received a much more complete development in England than in France, although in the latter country great efforts are being made to meet the necessities of this new photographic industry. The success obtained in this direction by Messrs. Kennett, Swan, Fry, and others, is both a proof of the excellence of the process, and a promise of continually increasing extension. With us, M. Stebbing has also obtained very good results, and he is constantly engaged in improving his appliances so as to render his production of these plates as rapid and regular as possible. He has just set up a gas-engine, by Bisschop, in his workshop, by aid of which the gelatine can be kept in continual agitation while there is added, drop by drop, the solution of silver nitrate which is to form the bromide maintained in the liquid in a state of suspension. By means of the same engine a current of air is established for ventilating the closet when the pellicle is put to dry. Notwithstanding the opinion of a certain number of photographers, who believe that the use of these new films can only become general when every one knows how and is able to prepare them themselves, I do not think that we shall ever reach perfection in the process until the preparation of the emulsion and of the plates becomes the special business of manufacturing houses who can carry it out on a large scale by means of the necessary appliances and machines; only by thus making the manufacture a speciality can be insured a perfect regularity and identity of production. What has been done in England is a proof of the truth of my assertion. For example, was not the collodion of Mawson and Swan highly appreciated, notwithstanding that—or, to speak more correctly, because—it was manufactured on a large scale and delivered ready for use? In a still

higher degree will this be the case with gelatino-bromide pellicle. Success is and will be the result of a manufacture which is thoroughly specialised, which is constantly being improved by methods rendered more and more perfect by practice, and on a continually increasing scale.

Rapidly Moving Objective Shutters Necessary with Highly-Sensitive Films.—Visiting M. Stebbing the other day, I was struck with a negative taken on gelatino-bromide, and representing a scene of persons and animals in motion. Among the latter was the figure of a horse with only three legs—the fourth was nowhere to be seen. This is what appears to have taken place. The time of exposure was about a second—merely open! shut! During this period the horse raised and brought down again one of his hind legs, and as this leg was in motion during the whole of the exposure, not one of its points had been kept in the same position long enough to produce an impression on the sensitive film. Thus, as will be at once comprehended, the picture, when developed, contained a tripod horse. This appeared to me to be a very remarkable effect; the fact certainly points to the necessity of furnishing the objective with shutters moving much more quickly than those worked by hand when plates of such extreme sensitiveness are employed. Guessing the time correctly when the exposure is a long one is not of importance—for example, when it extends over thirty seconds, there is not much harm done if it be cut short to twenty-nine, or extended to thirty-one seconds—but the inaccuracy may become injurious when the exposure is itself almost infinitesimal. A shutter, therefore, by which such minute differences of time can be made appreciable becomes a necessity, for there are many cases where an exposure of only one-tenth of a second is required, while in others three-tenths or even five-tenths may not be too long.* Without some apparatus of this kind, which, as it seems to me, would not be difficult to arrange with sufficient accuracy, we shall be liable to grievous failures when plates are employed of the extreme rapidity which is now so common. To obtain improvements of this kind, so beneficial to the art of photography, all the resources of science must be taken advantage of.

Alleged Inferiority of France in Photography.—This is a question which I have no wish to enter on fundamentally, for fear of being carried beyond the limits of the space assigned to me; but I may be allowed to use the liberty accorded to me by the Editor of the PHOTOGRAPHIC NEWS, in whose columns contributors are allowed to express conflicting views with complete impartiality, merely to state that I do not share the opinion of my respected colleague, M. Versnaeyen, as regards the position which this country occupies in the van of photographic progress. This opinion he expounded at some length in his correspondence published in the PHOTOGRAPHIC NEWS of the 22nd of August last. When he wrote this letter he was no doubt actuated by the wish to see France shining among other nations who are most advanced in the onward march of our art; there is equally no doubt that his statements and arguments were based on sincere conviction. But in regarding things among us in so unfavourable a light, he was not the less under the influence of an illusion. At first I had hardly considered it necessary to express here an opinion in the contrary sense, equally well founded though it be, and if I do so now, it is only because scandal, with its hundred tongues, seemed to give point to this charge of inferiority. Is it not notorious that this correspondence of the PHOTOGRAPHIC NEWS has been reproduced in the *Photographisches Wochenblatt* of Berlin? For me, science and art have no frontiers; as far as the subject of applying the human intellect is concerned, I am under the influence of completely cosmopolitan ideas; I hold that the fatherland of the mind of man is the whole world—that for it there is no

distinction of nationality. If, then, I hold an opinion opposed to that of my colleague, it is not that I am under the influence of patriotism, though such a sentiment would be quite in its place, but that I bow to the actuality of facts. The truth is that everywhere efforts are made in the cause of progress, and that each nation has its own position of superiority and its distinguished men, though they may be more numerous in one country than in another. England, for example, so far as its position on the path of progress is concerned, is in a very remarkable position, and I would not dare to put her, marching as she does at the head of our art, on a footing of equality with other countries who merely walk in her footsteps. Indisputably, the art of photography is there more diffused than anywhere else; but though I admit it, I cannot refrain from pointing out that among us in France there is plenty of emulation. We produce much work, and do not allow ourselves to be kept back further than the requirements of prudence would dictate by the difficulties attendant on new opinions; we hold in the photographic world a position sufficiently assured not to allow ourselves to be troubled by the words, "inferiority of France." Suppose a comparison is instituted between us and any other nation; suppose even that it be proved that in some point or other we are behind the rest; we have a complete compensation, for there are many points in which we thoroughly hold our own. Let me further only beg my esteemed colleague to ask himself whether he has not placed us too low down on the photographic ladder. My own conviction is that we deserve a better position than he has assigned to us; the esteem in which all French work is held by the people of other countries, and the consideration which is everywhere accorded by the photographic press to the productions of the countrymen of Niepce, Daguerre, and Poitevin, make the case still stronger in our favour.

The Papyrograph.—When examining the working of the papyrograph (an invention of Messrs. Luceato and Woolf, brought out, I believe, first in England), it seemed to me quite possible to apply the principle on which it is based to photographic printing. Considered from this point of view, the process appears to me to be quite different, both in a practical and industrial sense, from that of the chromograph, of which I have given a description in previous correspondence. In the papyrograph, a manuscript or drawing is made with a particular kind of ink on a piece of paper coated with some substance which the ink is capable of dissolving. The paper becomes permeable in those places where the coating (which I believe to be gum-lac) has been removed, and when applied to a velvet cloth impregnated with aniline violet, it imbibes sufficient of that substance to allow of the drawing or writing being transferred, by pressure only, to a piece of white paper; in this way about 500 copies can be drawn in succession from the original. Now this idea is a very good one, and could be easily, I think, applied to photography. All that would be required would be to transfer to the permeable paper a carbon negative, which, previously hardened with alum—or, better still, coagulated—would constitute an impervious reserve. The ink would only pass through the white parts of the paper, or through those more or less white; and thus a photographic copy would be reproduced, not only of the lines, but also of the shading. The practical application of this method appears to me to promise very well. I mean to try it, and will communicate the result to my kind and indulgent readers.

The Author's Hand-book of Phototypie.—Only a line to state that my new work has just been published by Gauthier-Villars. It does not become me to say anything concerning it further than to assure my readers that I have done my best to render it as complete as possible. I intend shortly to send a copy to all the photographic journals, as well as to all the leaders of the profession, and I venture to express in advance my gratitude both for their remarks and their criticism. LEON VIDAL.

* Mr. Swan's quick-acting electric lens shutter, described in the PHOTOGRAPHIC NEWS of the 15th of August, appears to realise these desiderata.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER IV.

THE FAROE ISLANDERS—ICELAND—HOWIE MAKES A SPEECH.

ON the third morning of our voyage we sighted the Farøe Islands—groups of sterile rock, frowning precipices at whose base the water broke with a roar like thunder, and on the top of which grazed a few shaggy-looking sheep—deep, dark fissures in the face of the inhospitable coast, into which the waves rolled and disappeared in a twilight of a spray—such is the general aspect of these gloomy and forlorn islands. Yet on those bleak, desolate rocks, two hundred miles from the nearest land, in the open of the wild Atlantic, lives a race of hardy, fearless men and women numbering upwards of eight thousand. Is it not true that one half the world knows not how the other half lives, and have we not reason to be thankful that we live in a land that can appreciate Board schools and photographers? Yes, these Farøe Islanders are far behind in civilization! They have not a single ale-house, nor the shadow of a shebeen, nor a druggist's shop, not even a grocery store! Every man there is his own shoemaker and his own tailor, unless he can prevail upon his female relations to do it for him, the result to his personal appearance being picturesque in the extreme. Ah! you grumblers, how would you like to live there? How would you like to feel in the morning when you awakened that your breakfast was still swimming in the sea, that your dinner was still on the wing, and know that if you did not look pretty smart you would have to go without either? Yet these islanders have something solid in the way of consolation to reflect upon as they crack their knuckles over their sea-drift fires—viz., they have neither rögde-money nor poor-rates to pay.

We unpacked our traps and went ashore for the purpose of photographing a group or two of the inhabitants. After an hour's hard hunting in such huts as we could find, and cheyving two or three young women who evidently looked upon us as pirates or something worse, we gathered three women and four men together. The men were sullen—sulky; the women were timid and frightened. We could not make them understand what we wanted. They had never heard of such things as photographs, and of course eyed our preparations with uneasiness. One old woman wept bitterly all the time, and got worse when Howie requested her to cheer up and look pleasant. "I do believe," quoth Tom, "that the old witch fancies we are about to send her to glory."

The boat's crew that landed us had strolled up to view our work, and, like seamen, were very free in their remarks, and I do believe their appearance helped greatly to unsettle the poor beggars we were about to photograph. Howie and I were busy with our dark tent (which, by-the-bye, was like everything else that Gilbey took with him, of immense proportions; however, it came in very handy latterly, when we were glad of its shelter o' nights), and Gilbey was busy setting up his tripod. The islanders watched him carefully. He next examined his camera and screwed it on the tripod: the islanders moved nervously. He then adjusted the lens: the islanders whispered each other. He then dabbed his head underneath the focussing cloth: the islanders, with one unanimous feeling, turned and fled, and in their haste upset the old woman, who screamed and pawed the air, as she lay on her back, in an awful manner.

"Heavens!" exclaimed Gilbey, who had been trying in vain to find their image on the ground glass, "where are they?"

"Gone to get the air, Mister," grinned one of the seamen.

"They have got some very pressing business on the other side of the island," quoth another.

"Shall we fetch them back?" asked a wicked-looking young fellow.

"Yes—yes—by all means," replied the puzzled Gilbey. "Call them back, by all means! What an extraordinary people!"

No sooner did Mr. Gilbey give his consent, than the sailors gave a British cheer that made the seamens flutter out of their rocky nests and scream with fright, and dashed off in pursuit of the natives. Meantime Howie had restored the old woman to her equilibrium, and, as we had a plate ready, we photographed her in front of a mud hut, "like Niobe, all tears."

After we had accomplished this, we climbed up a hill to look for our sailors and our sitters. Heavens! Did not Gilbey turn pale at the sight that met us when we looked over that hill? There were our sailors engaged in a stone fight with about forty Islanders. Yes, ye gods! and our sailors were retreating.

We rushed down the hill, and, as Tom Howie afterwards remarked, "we packed up our traps with the utmost expedition, and fled with the greatest bravery to the boat."

We were barely seated when the sailors rushed down the rocks in a body, pushed off the boat, and we left the Island of Stromsøe while the air seemed to rain profanity and stones.

After we were clear of the surf, and without reach of the stones, Gilbey crawled out below one of the thwarts, and asked, "But how on earth did it all happen?"

The sailors looked at one another, and were silent. At last one old fellow, who was busy trying to stop the bleeding of his nose, growled, "Well, I never; and after him a-telling us to do it, too!"

"What! I tell you to do it!" cried Gilbey.

"Didn't you tell us to fetch them back?" demanded the sailor indignantly.

"Yes—but—"

"Well, they wouldn't come," grinned the tar.

Poor Gilbey had a sorry time of it when we got on board. The story spread like wildfire, with all manner of additions and variations. The whole ship, from the cabin boy to the captain, knew it; the noble company called Gilbey into lunch, and enjoyed it immensely; indeed, had we got successful pictures of those miserable Islanders, it would not have bestowed half the satisfaction on the company as what the final disaster had. It was a merry night, that! The whole ship seemed to be possessed with the spirit of laughter. You could hear the cabin boy and steward's boy giggling, as they stowed away the crockery; the cooks splitting their sides; the captain and company haw-hawing, by Jove! while forward the sailors were roaring. Ever and anon a voice would exclaim, "Heavens! Where are they?" Then an answer, "Shall I fetch them?" followed by roars of laughter. Gilbey and the man at the wheel were the only silent and sorrowful beings on board that night. Gilbey had retired to his cabin under the plea of illness, and Howie seized the occasion to deliver his opinion relative to fat pork, and had a boot thrown at his head for his pains.

Out in the open once more! Three hundred miles of the rolling North Sea had we to cross before we could see land again: we would then be within the Arctic circle. We had beautiful weather; rather cold, but clear and sunshiny. We passed our time sitting on deck, smoking our pipes, watching shoals of puffy (blower) whales sporting on the rolling waves, and listening to the irrepressible Howie.

The voyage was only one thousand miles altogether, and I daresay some of my readers may sneeringly be remarking that I am making too much of it. I do not think I am. Independent of it being my first voyage, I was going to a country unlike any other under the sun. I went to a country where grain cannot grow—where there are no forests—where the trees never grow higher than a walking stick—where there are no flowers, no fruit, except a tasteless little thing of a berry no larger than a pea—a country

with no relics, no monuments of ages passed away, although it dates a thousand years—a country where you can behold Nature, without art—rude, unpolished Nature—Nature in her wildest and most fantastic moods.

In other countries you go to see wonderful architecture designed by geniuses whose names are sunk in the oblivion of time. You go and pay money to have Turkish baths; you enjoy hours upon hours in galleries representing the antiquity and wealth of the country; but here you have Nature supplying all these wants. You can obtain scenery that will rival the glens of dark Locknagar; you will find the remains of centuries' lava mushrooms. You will find wells that can boil an egg; lakes that have any kind of temperament you choose: if it prove too cool at the edge, you have only to swim where you see the steam rises, and you can get it as hot as you wish. You will find a most remarkable atmospheric phenomenon. The mountains at twenty miles' distance will appear but only three or four; and such is the magical effect of pure atmosphere that you are almost tempted to reach forth your hand and pluck the purple heath that grows on their rugged sides.

Who is it that has taken a voyage, either long or short, who has not felt the thrill of "Land ho?" You should have seen the crowding on deck, and the eager looks of our noble company, when the bleak coasts of our destination were descried. Our first landmark was the smouldering and smoking Mount Heckla; forty, fifty miles' distance we could plainly see it; then came the black, terrific coast, deeply indented by narrow inlets or fiords; bays, whose dark, unfathomable water were surrounded by cliffs under which our vessel looked but a toy.

By evening we cast anchor in the harbour of Reikiavik, the most northern of capital cities. The simplicity of this city of twelve thousand inhabitants strikes you with amazement. It may be described as two long parallel rows of streets: the houses built of wood, and only one storey high. Every house in the place is thickly coated with tar, the frames of the doors and windows being picked out with white, so that it has anything but a lively appearance; in fact, it is quite the reverse, and gives you the notion that it is in half-mourning for some distant relation. Still, in despite of the poor look of the place, there are plenty of good things to be had in it. Independent of the new hotel, that was then a two-storey building with a square roof running up to a peak, and the Governor's house—a long, low, sprawling affair built of lava—there was, or is, a very comfortable-looking church.

Here we landed and took up our abode at the hotel. In the evening we were invited to what Howie termed a "grand spread," by the Allthing the next in office to the Governor. It was the misfortune of all that we could not understand each other—there was not one there who could speak English, and we knew as much about the Danish language as the man in the moon. However, things went on swimmingly: our awful appetites helped to cover any mistakes we made with the dishes, and our strong heads resisted their drinks. At last, apparently, the feast was over, and to our astonishment the giver arose and delivered a thundering speech; having finished, another started, and so on until all had their say with the exception of us three Englishmen.

We had diligently given our applause to all the speeches, and emptied our glasses and filled them again with the boldness of Aldermen at my Lord Mayor's feast. But now there was a hitch in the performance. The Icelanders coughed, looked at each other, and then at us, in the most significant manner.

"See!" quoth Tom, nudging Gilbey, "they want you to make a speech!"

"A speech!" gasped Gilbey, in horror-struck tones. "What on earth can I make a speech about? I never made a speech in all my life, and don't know even how to begin."

"But you must make one," replied Tom coolly; "it's the least you can do, and they expect it from you."

Gilbey cast a helpless look around, and an appealing one to me; but I had never made a speech either, and felt anything but confident enough to make one now.

"You are a couple of nice fellows," quoth Tom sneeringly. "If the honour of old England reposed upon your shoulders it would soon come to grief. Give thanks that you have at least one eloquent tongue that can do justice to your fatherland."

With that Mr. Tom Howie rose with the utmost coolness, bowed smilingly to the company, commenced and gave Longfellow's poem of the "Skeleton in Armour."

"I was a Viking old;
My deeds, though manifold,
No scald in song has told,
No saga taught thee!"

The Norseman phrases in the poem evoked bursts of applause; in short, Mr. Tom had quite an ovation, and gained for himself a reputation for learning and eloquence that lasted out our stay in the country.

There are lots of reputations founded upon similar bases, and no one knows anything about it.

(To be continued.)

ART AND ITS RELATION TO PHOTOGRAPHY.

A SERIES OF PAPERS.

NO. II.

BY AN ART STUDENT.

THE first necessary and primary element in portraiture is grace of outline, which comprises not only the external limits of any subject, but everything contained therein, for lights and shadows must be adjusted with as great attention to their form as is bestowed upon the figure itself. And as herein lies the great source of successful art production—as without a knowledge of what constitutes the beautiful in outline all work must necessarily sink beneath the level of mediocracy—it will be as well to consider, as far as possible on paper, what outline proper consists of.

Before proceeding to discuss this, however, I would draw attention upon one point which is of the utmost importance, viz., that anything, no matter what it be, that is produced without study or effort, can never hope to rank for excellence. It is an utter impossibility that the result can be valuable. Therefore, if photographers labour under the belief (as they seem to do) that works of art are to be produced without much mental effort, as long as they continue to hold that opinion, so long then will their work remain as it is almost universally (at present), unable to compete with artists who have given and are giving the subject a life-long study.

The use of colour has been the great cry among photographers, and, to a certain extent, they are justified in making it an excuse, for colour, which is denied them, is undoubtedly a wonderful aid to popularity, covering many blemishes, and lending a charm to what might otherwise be unnoticeable and without interest. But the want of colour is no excuse for the want of art. We can allow the absence of the one, but not the other. Like education, there is no substitute for it. A man may be an honest man dressed like his fellows, and although uneducated, will, by his appearance, pass in his own circle; but the moment he associates with those above him in a mental sense he sinks at once to the level of the vulgar; and thus, with the majority of the photographs of to-day, they lack all which goes to make an educated production, and though, perhaps, pleasing the million, do anything but give satisfaction to those best competent to judge. Comparisons are invidious, and therefore it is not to be

supposed that this sweeping statement applies universally, as there are many photographers, happily, who are striving to make their work worthy of them, for mention could be made of many such. Yet these papers are written in the hope that those who aim at high art, who love it for itself alone, unconnected with sordid gain, may reap some benefit. Whoever practises the profession of photography with the main object of turning out as much work as possible, and pandering to the taste of the general multitude, need never hope to raise his art above its present level. The present prices are perhaps a drawback; but give us the glorious pictures teeming with mind, pictures that the eye can feast upon again and again, and if patrons are not found ready to purchase at a price which will compensate for labour, then the love for art and the beautiful will have passed away. When the painter places the virgin canvas before him on the easel, and, charcoal in hand, prepares to commence the picture, he has some definite object in view. The model has been placed in the position considered most suitable; the light has been carefully thrown, and the drapery, as well as the principal parts, most cautiously posed. There is a general outline, a completeness in the action, or repose of the model, which denotes something. The model is there representing something which has for its birth the brain of the artist. The figure or face has many unsightly parts which cannot be subdued by the shadows thrown. But the artist heeds them not; his imagination is busy; in his mind's eye he sees the scene he is portraying; every beautiful line of the figure is followed; every delicate curve of the rounded arm or cheek is sized and noted down; and when these are justly rendered, and brought out by all the means in his power, the ungainly parts are sunk and softened till we see them not. The draperies are made to throw up the salient points of the figure. The background also helps to tell the tale, and when all is finished, and the artist, though unsatisfied, can do no more, the eye rests upon the principal parts, and catches at a glance the intention he has attempted to depict. No twist of the arm, no thrusting forth of any minor part, tends to carry away the mind from dwelling upon what was meant to be the principal part of the picture. The was a photographic exhibition—I do not remember where—but there was one thing in connection with it which made a profound impression upon me at the time, and as it has a bearing upon the case in hand, I will mention it. A medal was awarded by the judges to a picture—a portrait it was—on the grounds that the drapery of the figure had been most excellently rendered. The notion struck me as being remarkably fine. I certainly never heard of the Royal Academy granting a medal for the able manner in which a coat or lady's dress had been imitated. As there were some artists amongst the judges, I am inclined to think it must have been a little piece of satire on their part. Nothing could illustrate my meaning better: the main feature in the portrait (the face, as it ought to be) passed over, and the drapery—the subordinate part—raised to the first rank. Let us have the face equally well rendered, and the dress can then be allowed, but not till then. Conquer the main difficulty. But he who commences by allowing paltry things to usurp the main feature of his picture is no artist. By years of patient study the threads in a linen cloth can be imitated one by one; but not so with the divinest of God's creations—the human form. And he who wastes the precious time dallying with the one, and neglecting the other, can never hope be recognized as a legitimate student of the fine arts.

In my next I will endeavour to show what ought to constitute a good photographic picture. The papers were originally commenced in this journal four months ago; but, owing to indisposition, have been delayed.

Correspondence.

POWDER PROCESS.

SIR.—Will any worker of this beautiful and permanent process give their experience in dissolving away the yellow bichromate after development?

I find a great difficulty in retaining the fine half-tones, they washing partly or completely away, leaving a hard, chalky image. In the old vitreous process of Lafon de Carmasac I found no difficulty, the collodion film firmly holding the pigment.

A CANNY SCOTT.

LUXOGRAPH PICTURES AT FALMOUTH.

SIR.—In reply to a letter in last week's issue by a "Non-Exhibitor," it is much to be regretted that a principle cannot be discussed without introducing individual names. I am not surprised at his taking a "nom-de-plume," as his statement is a breach of confidence. How does he know that the plate was prepared by the firm he mentions, or the enlargement done by a company?

Granting that his statement is correct, I consider I am in the same position as a firm (I shall mention no names) who take a medal for their operator's work. The company who do the enlargement are for the time being in my employ, the same as a first-class operator may be to a firm of photographers. Mr. "Non-Exhibitor" must be behind the times if he does not know that my case is not an isolated one, as the "Society of Great Britain" awarded last year a medal to a similar case.—Yours, &c.,

H. GARRETT COCKING.

Talk in the Studio.

ORNAMENTAL BORDERS.—We have received from Messrs. D. H. Cussons and Co. an example of gelatine negatives of ornamental designs for borders, making a card portrait into a cabinet by surrounding it by a well-designed border. Judging from the sample, these are very excellent, artistic in design, and perfect as negatives, with masked centre for printing borders. They are produced in Paris. We can with pleasure commend them to the attention of photographers.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The first meeting of this Society after the recess will take place on Thursday next, October 2nd, at 8 p.m., in the rooms of the Society of Arts, Adelphi. Papers will be read by Messrs. Cobb and Brittlebank.

RAPID PHOTOGRAPHING.—Mr. Muybridge's method of photographing horses in rapid motion has lately been applied in San Francisco to the study of human action, particularly that of athletes while performing their various feats. In order to display as completely as possible the movements of the actors' muscles, they wore brief trunks only while performing, and thus all the intricate movements of boxing, wrestling, fencing, jumping, and tumbling were instantaneously and exactly pictured. The first experiment was in photographing an athlete while turning a back somersault. He stood in front of the camera motionless, and at a signal sprang in the air, turned backward, and in a second was again in his original position, and in his very tracks. Short as was the time consumed in making the turn, fourteen negatives were clearly taken, showing him in as many different positions. The same man was also taken while making a running high jump. The jumping gauge was placed at the four foot notch, in order to give an easy jump, as in making it fourteen stout hempen strings had to be broken, as in photographing trotting horses. From the camera to a point beyond the line on which the jump was made a number of strings were stretched. The two base lines were only a few inches above the ground, and from them to the apex the strings were placed an equal distance apart. In jumping, seven of the strings were broken in ascending and seven in descending. The strings were tautly drawn, and so connected with the camera that as each one parted a negative was produced. Other pictures were taken of men raising heavy dumb bells, and the various movements of boxing, fencing, and the like.—*Scientific American.*

PRINTING ON GLASS.—The following method of printing on

glass may possibly be of service in many ways instead of the use of etching or grinding, now so frequently resorted to. The process, patented in Germany by Mr. V. Koeppe, consists, first, in obtaining a positive plate consisting of plaster of Paris, type-metal, cement, kaolin, &c., from a wood-cut or electrolyte. From the positive plate thus formed a negative is obtained, the preparation of which is as follows: 50 parts of good glue are soaked in 40 parts of water, 50 parts of glycerine are then added, and the mixture is exposed to gentle heat until the glue is dissolved. One part of olive oil is next added, the mixture is again heated to a boiling point, and now a cast may be taken of the positive plate. On cooling, the shape is retained, but it remains very flexible. It may now be attached to wooden plates or rollers, and is then ready for printing. By encasing the slender stem of the cast in a metal sheath, casts of single letters may be used as in the case of ordinary type. The colours are applied to the plates by means of rollers. The printing inks are composed of the desired shade of pigment, levigated with enough balsam of copaiba to form a paste of the consistence of butter, and to this Venice turpentine and 50 per cent. of semi-resinified oil of turpentine or lavender are added. Bronze powder may be applied immediately after printing, and the piece is then to be baked in an oven.—*Gewerbe Zeitung*.

MORE JOY FOR TOURISTS.—Outside a photographer's shop in Princes Street, Edinburgh, hangs the following announcement—"Highland costumes kept for gentlemen to be photographed in, and Newhaven fishwives' costumes for ladies."—*Family Herald*.

To Correspondents.

GRISNEZ.—No detailed description of the electric shutter has been published. The inventor is Mr. Cowan, 36, Porchester Terrace, London, W.

ONE WHO WISHES TO KNOW.—The earliest *carte-de-visite*—that is, the earliest portrait of that size—we have seen, was produced by Dr. Diamond in 1852. The earliest who gave the name and created the rage for the *carte* was Mons. Disderi, in Paris, in about the year 1859. During the following year they began to be the rage in this country.

S. COWELL.—The exhibition of the Photographic Society will open to the public on Monday, the 3rd of November, and to members, the Saturday evening previous. Friday, the 26th, is the last day for receiving pictures. All particulars may be had of Mr. E. Cocking, Assistant Secretary, 57, Queen's Road, Peckham.

G. L. F.—A collodion positive does not fade; but if it be exposed to the air without the protection of glass, it will tarnish and spoil. If it be well varnished this will not occur, but in any case it should be kept under glass the same as a Daguerreotype. There are many reasons why paper prints superseded glass positives. One important one is the possibility of rapidly multiplying copies. The fragility of glass was also an objection.

R. D. M.—We are sorry, but can scarcely help you. We cannot, with propriety, fill a large amount of space by reprinting, for the benefit of an individual, an old article which his carelessness allowed to be destroyed or lost in a back number. Most of the early YEAR-BOOKS are out of print. They can sometimes be obtained at an advanced price by advertising for them.

F. R. A.—You should be more explicit. Do you wish to take enlarged photographs of microscopic objects, or microscopic copies of large objects? In either case, you had better read some of the many articles which have appeared in the NEWS and YEAR-BOOKS on the subject. There is a brief, simple, and useful article on p. 56 of our YEAR-BOOK for 1866.

STAINER.—Mr. Woodbury is the proper person to apply to. Shall we forward him your letter?

GRISNEZ.—We do not know who supplies collodio-chloride material at the present time. Mawson and Swan used to do so, perhaps do still. 2. The article on clouds to which you refer appeared in the NEWS of August 31st, 1877. It is in print, and may be had by applying to the publisher.

COLLODIO-BROMIDE.—Many thanks. In our next. Too late for this week.

NORMAN MAY.—We cannot understand the omission, which shall at once be rectified.

J. M.—You may obtain acetone of a manufacturing chemist: possibly of Hopkin and Williams. It may be obtained in various ways: one is by distilling dried acetate of lead in a glass retort, at a red heat, with plenty of water supplied to the condenser; the acetone collects in the receiver. 2. The earliest numbers of the YEAR-BOOKS are out of print.

Busy.—You will not find any enlarging process on paper very rapid. If you had stated what method you were using we should have been better able to tell you if there were a more rapid process. A process published some years ago by Herr Sternberg is said to be very rapid. It is as follows:—The paper is prepared as follows:—

Rainwater	35 ounces
Tapioca	310 grains
Iodide of potassium	155 "
Chloride of potassium	620 "
Lemon juice	250 drops

The tapioca is first made into a paste with a small quantity of cold water, and the other materials are then added gradually, having been previously dissolved in the 35 ounces of rainwater, which has been made to boil. When cool, it is spread on the paper by means of two pieces of sponge, as in the preparation of arrowroot paper. If exposed to the atmosphere, this paper very quickly assumes a reddish hue, and marbled stains often show themselves on the surface; but these defects disappear when the sheets are sensitized. The silver bath is composed of—

Rainwater	35 ounces
Nitrate of silver	2 to 3 "
Citric acid	80 grains

The strength of this bath should be reduced if the negative be dense, and increased if the negative be soft. The exposure must be prolonged until the outlines of the picture appear on the sensitive paper. It is then developed in a solution composed as follows:—

Rainwater	4 ounces
Saturated solution of gallic acid	1 ounce

Immersed in this bath, the proof will there become gradually stronger, and will assume a sombre brown tone. It should be raised from time to time by the corners and examined. When it has attained sufficient strength, it must be taken from the bath, and made to float on the water bath, to prevent the gallic acid from sinking into the paper. After some minutes the sheets should be plunged into the water and well washed; it is then toned in an old gold bath; and, finally, it is fixed in the ordinary manner. After the mounting, the proofs may be treated with encaustic paste, or varnished if brilliancy is required. The following process is somewhat less rapid, but gives fine results. It is described by Mr. Waterhouse as employed in the Belgian War Office for direct printing. Thin Stienbach Saxo paper is salted by floating it for one minute on a solution composed of—

Chloride of ammonium	2 parts
Citrate of soda	2 "
Water	100 "

Sufficient citric acid should be added to make the solution just acid. The paper is then dried, and may be kept for use. To sensitise it, float for three minutes on a bath containing four or five per cent. of nitrate of silver rendered acid with citric acid. This operation and the drying must be performed in a perfectly non-actinic light, as the paper is very sensitive. The exposure under the negative varies from a few seconds to one or two minutes, according to circumstances. Develop as follows. Prepare stock solutions of—

A.—Acetate of lead	1 part
Water	100 parts
B.—Gallic acid	1 part
Alcohol	8 parts

To 4,000 parts of water 50 parts of solution A and 8 parts of solution B are added (if the weather is warm, or the prints have been over-exposed, a little acetic acid may be added with advantage), and the mixture is filtered into a large dish. The prints are immersed one by one, and constantly moved about, to ensure the even action of the solution. The detail gradually strengthens, and, after about a quarter of an hour, appears of a good black colour. They are then removed to a bath of hyposulphite of soda at 30 per cent., and remain in it with constant movement for ten minutes or a quarter of an hour, and are then well washed with several changes of water. No toning is necessary, but if required, the prints can be toned in the ordinary way. We have seen good results by the magnesium light with the following:—The paper was salted by floating on a solution containing 15 grains of iodide of potassium and 5 grains of bromide of ammonium in an ounce of water. The silver bath contained 60 grains of nitrate of silver and 10 minims of acetic acid to each ounce of water, and the paper was used immediately after floating on this bath, and whilst it was still wet. The amount of enlargement was about six diameters; that is, the head, in the negative of which the head and bust were produced, was about half an inch long, and was enlarged to about three inches long. The exposure was exactly thirty-five seconds, with the light from one piece of ribbon. No trace of the picture was necessary in the process; but on applying a hot solution of gallic acid the image rapidly appeared, and, after about three minutes' development, was fully out, at once soft, round, and vigorous, clean in the lights, and deep in the backs, and an exceedingly good enlargement was produced. With a hot developer the exposure is shortened, but the risk of fog and stains increased.

The Photographic News, October 3, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY IN AFRICAN EXPLORATION—COSTUME PORTRAITS—STUDY OF MOTION BY MEANS OF THE CAMERA.

Photography in African Exploration.—Photography is usefully employed by modern explorers. Major Pinto, the Portuguese officer, who has recently returned from an important tour through Africa, availed himself to a great extent of the camera to depict the scenes he passed through, and his photographs will naturally afford a valuable means of illustrating the volume he proposes to issue almost immediately. The first African traveller, we believe, who made use of the camera was Herr Gerhardt Rohlf, upon whose staff Herr Remele, a Berlin photographer of note, found a place. Our readers may remember an account, which we published in these columns, of Herr Remele's photographic experiences in Africa, which were exceedingly interesting, besides dealing with points of practical detail that would be invaluable to future travellers. Herr Remele travelled right across the Libyan Desert with his photographic equipment, for days and days over sandy plains, which were varied at times by smooth, molehill-shaped sand ranges, the travelling being as monotonous as it was fatiguing. Two points in his account we remember well: the difficulty of excluding sand from the plate-boxes and carriers, and the scarcity of good water. As to supplies of the latter, they were obtained from some sheik or important man of the village, who in one case filled the water bags with brackish water, a fraud that was never discovered until the caravan had gone a couple of days on its journey, so that its immediate return became imperative. The sand difficulty is one experienced by every African traveller; and at the time of the Abyssinian expedition our military photographers were powerless to prevent the fine particles from penetrating their apparatus. Mr. H. M. Stanley, who has once more started to explore the Congo district, has carried with him on the present occasion, we hear, a very complete set of photographic apparatus, and the wherewithal to practise the wet process. He has, as before, a boat ready to fit together for navigating the inland lakes, and has engaged a large party of natives to act as retinue. He has, however, preferred to change his name for the nonce, and this bit of mystery has already been the cause of his delay by officials on the coast. We do not know if any of the officers who have followed Cetewayo into his hiding places have been provided with a camera, but we may be sure that Pietermaritzburg, which possesses several capable photographers, will speedily send us home pictures of the vast tract of Zululand which is henceforth to be considered under British jurisdiction. Natal is one of the most picturesque mountainous districts known to travellers, and from all accounts scenery in Zululand is still more grand in respect to its gigantic cliffs and forest grown ravines.

Costume Portraits.—An odd announcement by an Edinburgh photographer, which has been copied into a good many journals, to the effect that "Highland costumes are kept for gentlemen to be photographed in, and Newhaven fishwives' costumes for ladies," contains a good deal of common sense, after all, for nowadays it is, so far as ladies are concerned, quite the fashion to attire oneself as a shrimper at the seaside. At any rate, it is a custom among the fair aristocrats that frequent French watering places. We hear of duchesses in striped petticoats and bare feet, the shrimping net held in jewelled fingers, who take a turn on the sands every morning, while other ladies beguile the time in crab hunting among the rocks. Everybody must have felt how delightful it must be to patter about upon sea-weed and among the little pools in the rocks at low water; and now that the pastime has become a fashionable one, we can all join in it without being ashamed to be caught at such sport. Moreover, if the occupation gives ladies

an opportunity of wearing pretty costumes, to say nothing about showing a small white foot on the yellow sands, there is yet another reason for our amateur fishwomen. The bonnie fishwife herself is something of a fraud, or at any rate an exaggeration, and it will be very nice to see picturesque costumes set off at their best. The firm of Braun, of Dornach, who do a large business in the production of costume pictures from small cartes to twenty and thirty-inch pictures, and whose Swiss series includes more than a score of different dresses, soon found out that the native element did not satisfy their wants. When you have found a pretty girl in a pretty costume in the Canton of Berne, or Lucerne, or Appenzell, the chances are that she objects to be photographed. A costume in Switzerland is a costly affair, with its lace and silver chains, and the pretty girl who wears a pretty costume, therefore, is usually a woman of mark and position in the district, and would scarcely like to have her portrait exposed everywhere. So M. Braun overcame the difficulty in a very sensible fashion. He chose half a dozen comely models, and had these fitted with the different Cantonal costumes. The latter were made with great accuracy, and for the most part on the spot, so that they might be correct in every particular, and the models, suitably dressed and with suitable backgrounds, were then all photographed in the studio at Dornach. The results of such a system could not be surpassed. M. Braun's models were either Swiss, or from the borders of the Republic—Dornach itself is but a few miles from Basle—and the costumes they wore were the most perfect that could be procured. In fact, any of our readers who are unacquainted with M. Braun's Swiss costume series will do well to glance through the magnificent pictures he has prepared. One of the series consists of twenty-inch portraits or thereabouts, and these, elegantly coloured by a staff of artists at Dornach, sell largely in Paris and other capitals. Several pounds a-piece are charged for these magnificent productions; but the same pose and costume may be purchased in carte form for half-a-franc. Our Edinburgh friend seems to be going a step further, and asks the purchaser who desires to buy a photograph of a costume to have himself photographed wearing it. There would be no difficulty in this so far as ladies are concerned, for they would seem to have no choice but to be dressed as Newhaven fishwomen; on the subject of kilts for the gentlemen, however, a difficulty, we suspect, would sometimes arise. What would a Macpherson or a MacNicholl say (by the way, we heard in Scotland lately that there was no such thing as a MacNicholl tartan) if they saw Mr. John Smith, of Camberwell, wearing a kilt of their clans? It might be a question of claymores and bloodshed, and Mr. John Smith's conscience would be never easy after he had once consented to sit or stand in a kilt. There are, however, plaids that are not claimed by clans, and as these are open tartans, as they may be called, have usually a good deal of red about them, and consequently are very striking. We recommend sitters who must be taken in Highland costume to choose one of these.

Study of Motion by Means of the Camera.—As the taking of instantaneous photographs of men and horses while undergoing certain work is attracting some attention just now, it might be well to inquire whether electric illumination would not greatly facilitate the operation under some circumstances. The trotting of a horse, or the motions of an acrobat at certain periods, are some of the problems that have been put before the photographer to solve with his camera, the instrument being opened and shut by means of strings or wires moved during the performance of man or animal. A momentary electric flash might serve the same purpose, probably. Many years ago, a revolving fly-wheel was photographed by an electric flash in this way, the exposure being so quick that in the picture the wheel seemed at rest. Where, therefore, phases of motion are under study, this means of illumination might possess advantages.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER V.

WORK IN ICELAND—JAN, HIS DOG SLOKOS, AND THE BEAR—
"RELIGIONE ET BONUS MORIBUS."

HERE is my fifth paper, and I declare I have only landed my readers in Iceland! In the original design of these sketches I had by this time landed you all safe in old England again, and was about to introduce you to new characters and new scenes, but now I find that my "Lookings Back" cannot be treated in such a manner; in short, they must have their time. Fain would I know what my readers' opinions are concerning them, and I tremble while I breathe the wish? Fain would I keep you all a little longer in that fascinating land in the Arctics! I should like to tell you about boiling wild-geese eggs in the pools of the Great Geyser: to describe the wilderness of sterile rock by which they are surrounded, the strange unearthly subterranean rumblings that precede the weekly discharge of boiling water from those wonderful wells! I should like to take you to the north coast, where the Greenland winds, laden with icy perfumes gleaned from its continent of glaciers, might sweep round you, pinch your ears, and paint your nose a deep but undesirable blue. I should like you to gaze with me at the two wandering icebergs that have grounded on the rugged coast—to photograph with us those glittering castellated forms—to climb them—to share our terror when we discovered a bear, a real live polar bear, "fresh from his native woods," as Howie declared, ensconced in a deep chasm on the largest berg.

Yes, my friends; I am determined you shall stay a little longer with me in the land of ice!

For the first few weeks we had very unsettled weather, and had to work hard under the most distressing circumstances: sometimes being drenched to the skin by a sudden deluge of iced water; it did not come gradually or in drops as in other Christian countries, but at once without warning, and in sheets sousing you in a most effective manner. We had oil-skins and furs, but we would have wanted chain-armor at times; for after the rain would come a wind that would pierce anything softer than steel: this wind was generally accompanied by small hail of the most inveterate and tormenting qualities that ever fell from the clouds. It got in your ears, in your eyes; if you did not tie the feet of your oil-skins it was half way up your legs in a minute; and if you opened your mouth to swear or reason with it, it went down your throat wholesale, like an iced drink. After it was over we would commence and swab it out of the cameras, pick it out of the lens, thaw it out of the bottles, and make haste to get a negative before it would begin again.

The noble company didn't like it! Some of the youngest and most foolish made bold attempts and joined our caravan upon several occasions; but they were led home with strong symptoms of a speedy dissolution about them. Then we had it all to ourselves, and the noble company stayed at home, feasted, played cards, and speculated which of us poor beggars would be the first to die of cold. I assure you we were objects of great and deep interest when we returned at night. Jan, our body-servant and guide, I think, divined the feeling of the noble company, and used to marshal us proudly into town wearing a look that said plainly: "Look here! Look here! Is it not wonderful? I have brought them all back alive once again!"

I must introduce you to Jan. He was chosen by the governor as being the best guide we could get. He was sober and honest, knew all the wonderful places on the Island, and, above all, could speak our language. Of the last-named accomplishment the least said the better: suffice it to say that it was a source of endless amusement to Howie, who, whenever a halt occurred in our work, took occasion to improve Jan's English. Jan was a true type of an Icelander: stunted in stature—broad-faced—blue-

eyed—good-natured and kindly in disposition. Jan was the possessor of a faithful four-footed follower—a fox-hound, common on the Island, but more so, and in a wild state, I believe, on the Island of Jan Maine, at the entrance of the Straits. This dog of Jan's was pure white, with sharp teeth and a fine scent for game. It was Slokos' beautiful scent that discovered the bear in the iceberg before alluded to. Jan was in ecstasy—he danced like a madman, and hugged his dog and wept tears of delight.

"Behold! behold!" he cried in a burst of emotion. "Fine hound—fine scent—sweet smell—him snuff up a Polar bear! Clever Slokos! Him smell—him stink up the bear! Ha! ha!"

According to Jan there never lived a dog with so wonderful a scent as Slokos. If we came upon a spring well, and Slokos ran to lap at it, Slokos had scented it from afar. If we came upon a set of wanderers, or a stray hut, Slokos' defining nose had led us to them. He scented some wonderful scenery; he scented the boiling wells; he even scented the icebergs, and it now was only a little matter to scent the bear.

We had been on the Island over a month when the incident of the bear occurred. We had got clear of the vile weather, and had been enjoying something very like a tropical warmth. We were now in the middle of an Icelandic summer, and could see the sun the whole night long if so inclined. We took some remarkable pictures between twelve and one o'clock on one occasion.

It was on a Sunday afternoon, when we had made a little journey of a retrograde movement, in order to view once more our friends the icebergs, that we discovered the bear. Our camp was about fifteen miles inland, and we had come upon our ponies—we had no less than seven of these hardy quadrupeds in our little caravan—and while Jan, Howie, and myself dismounted to have a scramble on the bergs, Mr. Gilbey chose to sit on his horse's back and view us from the shore. Now it is worthy of remark that Gilbey's horse ran away with him at the very moment that Jan was caressing his dog, and that Howie, with a frantic yell, made known the presence of the bear. I do not mean to insinuate anything; I merely mention it as a very strange occurrence, especially as at all other times that horse, being a little broken winded, showed a greater tendency to lying down than running away. But there is no accounting for freaks of the animal creation, else how did the bear come to be on a wandering berg, three hundred miles from its native shores?

Jan, after he had done weeping and kissing Slokos, unslung an old flint-lock rifle that he always carried with him, and while he ostentatiously inspected and shook some powder into the pan, he declaimed, "I will quick discharge" 'im. I will bake death in bruder!"

After this he crept to the edge of the chasm, and laying himself flat down, commenced snapping his piece at the bear. He snapped it ten times with no effect.

"Hadn't you better put a lucifer in it, Jan?" asked Howie.

"Go 'way! You stir me up! *You spoil mein sport!*"

At length, about the twentieth trial, Jan's warlike relic went off with a roar like ordnance, and, truth to tell, the bear was no more. A poor skeleton of a bear it was—a mere frame—it had been living upon a hopeful nature for some time past, but hadn't thriven. However, Jan was loud in its praises—in his own praises—in his dog's praises. It was a great bear, and had a splendid skin; his (Jan's) heroic conduct should be reported, and the wonderful powers of Slokos' nostrils should be sung in song! Jan delivered this in broken sentences, as he dexterously skinned the unfortunate wanderer. Howie sat silently watching him on the edge of the chasm, laying the foundation of many a wonderful and thrilling tale to be told amidst his gasping friends when they sat round a candle with a long snuff on winters' nights.

On our way home we suddenly lighted upon Gilbey, sitting quietly, trying to light his pipe. "Let's make be-

lieve that the bear is after us!" cried Tom; and urging our horses to full speed we gesticulated violently, and roared with all our might, "The bear—the bear!" And, singular to tell, Gilbey's horse ran away with him for the second time that day.

A few Sundays after the above occurrences we were encamped at Bufell, a miserable village of four or five families, situate at the base of Mount Heckla. We had been working hard—sometimes with the noble company, and sometimes by ourselves. The summer was already gone; the nights were getting dark, and the aurora borealis increasing in splendour. Two months of summer! That is better than we have experienced this season, is it not? But soft! I will not wander—my space is limited. Ring the bell! Let the curtain rise to the slowest music; lights down; moon rising over the crest of the distant Heckla, and silvering the intervening lake of Thingvalla; tent and smouldering camp fire in the c.; Jan asleep on his bear skin, L; Howie and self discovered half asleep, R.

A dazzling meteor makes us start! I light my pipe, and Tom pokes up the embers, and by their flicker I observe traces of tears on his cheeks. He sees my look of surprise, and smiles as he holds forth a hand.

"Every one has two sides to his character, Geo," he says at last; "you thought I could know no sadness; I daresay you thought me incapable of soft feeling! You thought I lived on the surface—that I was all sparkling froth! Well, I have not any deep sorrow to brood over; but when the Sunday's quiet comes upon me, then I think of other Sundays, when motherly eyes looked their deepest love on me; when a sweet voice iustilled into my soul the seeds of goodness, that I sometimes think have grown so stunted! In such moments, Geo, I feel so little—so lonely—so—so queer; I cannot explain to you—but, softly in your ear—at such moments I can see my mother—see her, Geo!—see her as plainly as I see you now, only she is radiant and white, with a halo of light round her; then—then I know intuitively that, lightly as I take life, I have not long to stay!"

I was not very much astonished at this simple, serious outburst of Tom's. Several times I had observed him silent, absorbed in thought; I had even heard him sob, but directly he saw or heard us, the gloom left his brow; his blue eyes sparkled, and his ready tongue was rattling along as lightly as ever!

Tom was silent; and I clasped his hand. I would not trust myself to speak. Remember, I was young, and a thousand miles from home. Aye! Even had I been as old as I am now, I am doubtful but what I might feel the same. I hope I should, for I would not give a crack of my thumb for a man whose heart is all worldly and hard.

"I am afraid I have given you the blues, Geo!" quoth Tom, as I sat in thoughtful silence beside him. "Now I must bring forward the other side of my character, and brighten you up. While I was sitting here looking at the dying embers, and buried in my sad reminiscences, I was half inclined to burst out laughing: they say it is but a step, you know. The thought flashed upon me of the way in which a school was chosen for me. My father was a coachman, and had himself a very limited education. My Uncle Toby—who is alive yet—is a horse dealer, shrewd and sharp as a needle; but signs his name "X, his mark." Well, mother having died, the two brothers laid their heads together, and had a deep consultation about my future welfare. One thing they both resolved upon, and that was to give me what they had not themselves—a good education. 'What school shall we send him to, Toby?' asked my father. 'Blow'd if I knows,' was Toby's eloquent answer. 'But I'll tell 'e, Tummas, let's go round town and spect a few ou em, then we can pick the best.' So accordingly father and Uncle Toby went and visited the schools. One school was too little; another had a school-master whose manner they did not approve of; one had this fault, and another had that, until the afternoon approached, and still

they had not discovered the arena of knowledge that was good enough for their little trust. At length they came to an institution known as Dr. Canelinn's Academy. The Doctor considered himself anything but small drink, and took every opportunity to let the public know the principles he employed in carrying on his profession. Thus it was that he had printed in a wreath that spread all over his school house, in gold letters, the motto: *Religione et Bonus Moribus* ("Religion and Good Morals").

"This here seems a proper place," cried Uncle Toby, wiping his forehead. I've no doubt he was getting tired of the job by this time.

"'Wot's that?' asked father, pointing to the gold letters.

"That cre's the motter," answered Toby.

"Hum! Motter! What does it say?" and father put on his specs and spelt it out the best way he could. 'Hum! hum! "Really Johnie eat bones and murphies." Hum! Is that what they calls a motter, Toby?"

"Ha! ha! ha!" roared Uncle Toby, holding his sides, 'Ha! ha! ha! "Really Johnie eat bones and murphies." Well, that is good! That would be a proper motter. Can't thee see, brother, that it reads—"Real guano, bone manure." There's sense in that motter, brother—good sense, and that is just wot we want to teach young Tummas. So take my advice, and send him here.'

"So I was sent to Dr. Canelinn's. But look here, Geo! don't you think there are a great many people like old Uncle Toby—eh?"

(To be continued.)

PHOTOGRAPHY AND THE SUN'S SURROUNDINGS.*

WE take next a brief description of the rays as seen by Mr. Alfred C. Thomas, from Capitol Hill, near Denver City. "In the plane of the ecliptic," he says, "the streamers of light extended for about $1\frac{1}{2}$ times the diameter of the moon." Three accounts, then—Mr. Lockyer's General Myer's, and Mr. Thomas—agree in describing the extension of the rays in the direction of the ecliptic. We might quote other accounts, for, in fact, many observers saw these ecliptic streamers. They were seen by so many as to leave no doubt of their reality. We have now, however, to consider the evidence of those who saw these ecliptic rays to a much greater distance, and of one observer who saw also rays at right angles to them which other observers failed to recognize, but which must not on that account be regarded as subjective phenomena.

Professor Cleveland Abbe had intended to observe the eclipse from Pike's Peak, but he was taken ill a short time after reaching the summit, and had to be removed to the Lake House (hotel) on the day preceding the eclipse. Here, without instruments, and too ill to sit up, he made his observations. He could do nothing but observe the corona with the naked eye; but as he gave his whole attention during totality to the coronal rays, his observations are very valuable. By Monday, the day of the eclipse, he had recovered sufficiently to be laid on the ground upon a gentle slope facing westward. He says:—

"I was undisturbed by any other consideration, except to get a true presentation of the rays, which I had hitherto firmly believed to be either in the earth's atmosphere or in the observer's eyes. I went over the region around the sun again and again, at least six times leisurely, during the 161 seconds of totality, and cannot doubt the truthfulness and fairness of my drawing and description."

He saw the streamers which other observers had compared to a wind-vane; but he traced them to a much greater distance than other observers. The point of the vane, as he saw it, reached to a distance from the sun equal to fully

* Continued from p. 459.

six diameters. (A weekly contemporary says six degrees, but Professor Abbe's description and picture, both which we have before us as we write, agree in making the distance six diameters.) This would correspond to more than five million miles. On the other side, the double streamer forming the tail of the vane does not extend (in the picture) nearly so far, not more than three or four diameters, or about three million miles. The breadth of the vane where it crosses the sun is almost exactly equal to the sun's diameter, so that the sides of the vane just touch the sun's edge. Athwart the wind-vane streamers, at right angles, and forming a very similar system, lies another set of streamers, a pointed one above the sun corresponding to the pointed eastern end of the wind-vane set, and a broad, rather fanshaped streamer below the sun corresponding to the broad western end or tail of the wind-vane. The pointed ray extends fully five diameters from the sun. Its light was fainter, which accounts for its having escaped the attention of other observers with less time at their disposal to study the corona with the naked eye. It is very important, especially in connection with the choice of methods for observing future eclipses, to note Professor Abbe's experience on this point. He says:—

"All the details came out only after repeated examinations of the corona, and repeated attempts to draw and note its peculiarities. I am satisfied that a glance of a few minutes will no more suffice to do justice to these delicate phenomena than it could to enable a naturalist to draw the distinguishing features of a new shell or insect, or would enable an artist to correctly sketch in a landscape."

We can, then, understand why other observers, even some who recognized a yet greater extension of the coronal light, failed to perceive the fainter thwart system of rays seen by Professor Abbe. We also perceive that these thwart rays cannot possibly be rejected as merely subjective phenomena. They were seen by Abbe as satisfactorily, and remained as persistently visible, as the ecliptical rays which so many saw; but, being fainter, they were not detected by those who (like all except Abbe) gave only a short portion of totality to the study of the corona with the naked eye.

Only Professors Langley and Newcomb saw the coronal light extending further than the long rays observed by Professor Abbe. Langley, an astronomer to whom we owe the finest drawing of a large sun-spot ever yet seen, was at the head of a party from Pittsburg. Like Myer, he observed the eclipse from the summit of Pike's Peak. We do not know whether he adopted any special method of observing the faint outlying part of the coronal luminosity; but he traced it in the most transparent atmosphere to a distance of 12 diameters of the sun on one side and three on the other. Its extension was in the direction of the ecliptic, and the light resembled the zodiacal. In other words, what Langley saw at a distance of about 12 diameters from the sun was a faint and softly-graduated luminosity, not the separate rays seen to a distance of about six diameters only. Newcomb saw a similar luminosity, and traced it to the same distance from the sun. Like Langley, also, Newcomb seems not to have specially observed the long rays seen by those who examined attentively the regions closer to the sun. As Newcomb used a screen which concealed these regions from view, during at least part of the time devoted to observations with the naked eye, we need not be surprised that he failed to see features which Cleveland Abbe, studying these regions alone during the whole of totality, found sufficiently delicate to require his whole attention.

From a comparison of all the observations the following important conclusions seem established beyond all possibility of doubt or question:—Outside the solar sierra, averaging some 6,000 or 7,000 miles in height, comes the prominence region, extending about 100,000 miles from the sun's surface. Outside this comes the inner corona, shining in part with its own light, sometimes coming chiefly from

multitudes of solid or liquid bodies in a state of incandescence, sometimes chiefly from glowing vaporous matter. This region extends from 200,000 to 500,000 miles from the sun. Beyond the inner corona is the outer corona as already known and photographed during the eclipses of 1870 and 1871, and extending about a million miles from the sun. But far outside the outer corona there is a region occupied by matter so situated and so illuminated (or possibly self-luminous) as to present the appearance of long rays extending, if we may judge from observations hitherto made, directly from the sun to a distance of 5,000,000 miles. Outside this region again lies another in which, whether by the combination of multitudes of such rays as are seen separately close to the sun, or through the presence of matter in other forms, a softened luminosity prevails which during total eclipse can be traced along the zodiac at least 10,000,000 miles from the surface of the sun. Lastly, from observations made during evening twilight in spring and during morning twilight in autumn (at which twilight hours the zodiac near the sun is most nearly upright during the year) we can trace the extension of the zodiacal luminosity seen by Langley and Newcomb, to distances exceeding seven or eight times at least those to which they traced it during total eclipse. Nay, there are reasons for believing that at times this luminosity has been traced to such a distance from the sun as to show that the zodiacal matter extends much further from him than the orbit of our own earth.

(To be continued.)

SOME FUNDAMENTAL POINTS TO BE OBSERVED IN CARBON PRACTICE.

DR. VAN MONCKHOVEN gives the following hints:—

1. Formula for the sensitizing bath:

	During Summer.	Fall and Spring.	Winter.
Temperature	15 at 30° C.	16 at 22° C.	10 at 15° C.
Bichromate of potash	... 200 gram.	... 250 gram.	... 300 gram.
Carbonate of ammonia	... 30 ,,	... 15 ,,	... 10 ,,
Water	... 10 litres	... 10 litres	... 10 litres

In the summer, during hot spells, renew the bath twice a week; in winter time only once. Old baths yield grey proofs and insoluble films.

2. Never neglect the addition of carbonate of ammonia, this salt securing the solubility of the paper in the drying process. Non-solubility results in a lack of adherence when transferring on glass or paper; also in difficulty of development, tearing off the film in patches during development, &c.

3. Keep the bichromate bath in a cool place, and also sensitize the paper in a cool place. It is useless, during the summer, to add ice to the bath, for, unless a large quantity is added, and that in small lumps, no lowering of temperature will be obtained thereby, as the air warms up the bath as fast as the ice cools it down.

4. The carbon paper, whether in summer or winter, must be immersed fully three minutes in the bichromate bath; it is then to be slightly scraped to extract from it exactly the excess of bichromate, so that the sheet will not drip any more. If scraped too hard the pictures will lose their half-tones when developing. If not scraped at all, the gelatine will, during warm weather, melt while drying. If the carbon paper does not remain long enough in the bichromate bath, it will be deficient in sensitiveness; the half-tones will not stand developing; every defect of evenness in the film will appear, and it will be found impossible to develop satisfactorily plain tones or graduated white backgrounds.

If the weather is very warm, the gelatine will run off at the bottom of the sheet. When this is the case, lay it flat

upon a piece of dry cardboard, and set it to dry in a horizontal position.

5. Effect your drying in a draft of air.

6. To avoid shrinking* during summer, use simply very cold water (below 13° C.) to soak the papers in after exposure, and keep them under the water while they absorb it. If they are allowed to come to the surface, they absorb heat from the atmosphere, and will shrink.

Carbon paper soaked in water, after exposure, must curl up slowly when taken out. If it curls up quickly, the image is liable to shrink.

During summer, cold water must be used directly from the well, and used immediately; it will have sometimes to be made still cooler by adding ice, crushed into very small lumps, as large ones dissolve slowly, thereby failing to cool the water fast enough, because the air tends to warm it up again rapidly.

Simple transfer papers, or plates upon which are transferred prepared papers, must not be soaked in such cold water, and a separate dish may be used.

SILVER SOLUTION FOR ALBUMEN OR PLAIN PAPER.

BY JOHN R. OLEMON.†

MAKE a solution of nitrate of silver in water, up to required strength, and render it perfectly neutral. Then to each ounce of solution add 2 grains of nitrate of potash, and not less than 3 grains of washed chloride of silver—3 grains is the lowest quantity that should be used, but a larger proportion would be more beneficial, the quantity being limited only by the amount of room it occupies in your bottle, 10 or 15 grains to the ounce being none too much. Shake the whole well together, and expose to sunlight until the precipitate becomes darkened, occasionally shaking or stirring, so as to bring the whole mass under the action of light. When the darkening process is accomplished, the clear solution is ready for use, and is undoubtedly as pure a silver bath as can be obtained. The slight acidity arising from the action of light upon the chloride should not be neutralized.

This bath never requires boiling or "fixing;" excepting, of course, that the chloride will decrease by continued use, when it will be necessary to add a fresh supply. When work is done, pour your solution back into the bottle containing the precipitate, shake well, and place in sunlight. This is all that is necessary.

If, however, you should prefer filtering your solution, you will perhaps find a slight discolouration, arising from the extreme sensitiveness of the silver carrying some organic matter from the filtering paper (few brands are really "chemically pure"). In this case pass your solution again through the same filter, and it will be perfectly clear. Paper silvered on this solution keeps well even in hot weather.

In addition to the above I prefer to add a small quantity of glycerine to the bath in the proportion of 1 ounce of pure glycerine to 12 ounces of solution. It will be found to add very much to the brilliancy of the prints, and prevents the paper from curling so badly when drying.

Almost any good toning formula will do: perhaps the ordinary "sal soda" bath is the most reliable, if made fresh every day, and made up a few hours before using.

Hypo	1 part
Water...	8 parts

Fix ten to twelve minutes, keeping prints in motion during the whole time.

Fume from fifteen to thirty minutes, according to the size of your fuming-box and the condition of the atmosphere.

* Retraction or shrinking is a defect which is observed when the image is being developed, and while drying. The coating is dull by reflection instead of being bright, and it is entirely withered, and as if covered over by a black web, which destroys all fineness in the picture.

† *Practical Photographer.*

PHOTOGRAPHY OF THE SPECTRA OF GEISSLER'S TUBES.

BY DR. VOGEL.*

THE spectrum of hydrogen, which appears to the eye to consist of only four lines, showed when photographed upon gelatine plates, besides these four lines, hundreds of lines in the blue, violet, and ultra (invisible) violet. Many of these are light and delicate, while some are of extraordinary density. Among these are, besides the mercury lines, four lines in the ultra violet and one which coincides with the thick first H line of the sun's spectrum. The length of the undulations of the lines was measured, and their position as respects the Fraunhofer lines of the sun's spectrum determined.

The spectrum of mercury in the Geissler tube furnished in the photograph, besides the remarkable lines in the blue and violet which Thalen saw and measured, a surprising group of lines lying far into the ultra violet (length of the wave of the outermost, 3650). The spectrum of the mercuric spark in the open air coincided in many points with the spectrum of mercuric vapour in the Geissler tube, but it also differed from it in a surprising way. Thus, in the spectrum of the Geissler tube, the distinct line close by H in the violet was absent, while on the other hand, in the violet and ultra violet it showed a variety of bands which were not present in the spectrum of the spark in the open air between the poles of mercury.

The spectrum of nitrogen in the Geissler tube furnished a very characteristic photograph, with magnificent lines in the violet and ultra violet. Several of the latter far exceeded in intensity the visible lines in the violet. The appearance of the lines in the photograph was quite different from that which is given to them in ordinary drawings; they formed no simple shaded-off bands, but sharply defined lines, at the most strongly refrangible side of which lay a weak, washed-out looking band.

The nitrogen lines in the pale blue, which appear strongest to the eye, exercised but a slight action on the photographic plate, and on the green lines even a slighter.

If nitrogen and mercury be both inclosed simultaneously in the same Geissler tube, with a spark, one gets the lines of both elements; but if the tube be warmed, the nitrogen lines disappear and only the mercury lines remain. This has already been observed by Herr C. Wiedemann. Thus, if one were to photograph upon the same plate the spectrum of a nitrogen tube containing mercury in a cold and in a warm condition, he would easily get the spectrum of nitrogen and that of mercury together, and by comparison he would be able to recognize which lines belong to one element and which to the other. The nitrogen spectrum reaches as far into the ultra violet as the mercury spectrum.

Then I photographed the spectrum of an electric spark struck through atmospheric air, oxygen, and carbonic oxide gas. Thus upon one and the same plate we had all together the spectra of oxygen, atmospheric air, and carbonic oxide gas. The comparison of the pictures showed that the carbonic oxide gave by preference oxygen lines, and that by the spark it was decomposed into oxygen and carbon (the latter was actually visibly drawn out to the poles).

It was further observed that the spectral lines which are ascribed to the atmosphere are very different in character according as the different poles are used. For example: the spectrum of the air between mercury poles is very matt and undetermined; that obtained between platinum and aluminum poles is much more brilliant. Many of the lines in photographs of spectra of the air obtained in this way coincide, but many others do not, showing undeniably that the spectrum of one and the same substance may suffer by the presence of modifications which are very likely to arise. The changes in the spectrum of certain elements—as calcium, lithium, iron—which Lockyer ascribes to a decomposition of the elements, should therefore rather be attributed to the influence of foreign substances.

EXAMINATIONS IN PHOTOGRAPHY.

If endowment and encouragement were the sure aids to the advancement of scientific knowledge which they are fondly believed by many to be, science ought to progress rapidly in our day. It has been not uncommon in different periods of history to raise outcries against the alleged indifference of Government, and against other bodies in power, for withholding countenance and encouragement to science. We find Sir David (then Dr.) Brewster, just about fifty years ago, lamenting with pathetic earnestness that science was unrecognized and uncared for in high places in this country, adding the seathing remark that England had "renounced by Act of Parliament her patronage of the sciences most intimately connected with her naval greatness," in which he referred to the abolition of the Board of Longitude in 1828. We have no intention, however, of entering into the discussion as to whether science or knowledge generally flourishes best under the influence of the patronage of great ones, or whether it languishes and grows faint as it loses its independence. Complaints have not been unheard in our day of the niggard endowment of science, and to the effect that places of profit in the conduct of the State are rarely given to scientific men, to whom income and leisure would be beneficial inducements to aid in the advancement of science by which the country would be the gainer. We do not share in the spirit of these complaints, but have no intention to discuss them. We were led aside for a few moments in contemplating the encouragements to students offered by the multiplied facilities for examinations and the inducements of prizes offered.

We have just received the programme for next year of the Technological Examinations projected for the advancement of technical education by the City and Guilds of London Institute. In this programme our readers will be interested to learn that photography forms one of the subjects for examination and the distribution of prizes.

The City and Guilds of London Institute for the Advancement of Technical Education will afford facilities for carrying out examinations on certain subjects specified in its programme, and provide liberal prizes for efficiency in the students throughout the kingdom, provided local committees will undertake to carry out the examinations according to the rules laid down. The committee of any Art or Science School under the Department at South Kensington, or any School Board or Local Examination Board connected with the Society of Arts, will be accepted as suitable for carrying out these examinations.

The examination will be in three grades:—I. Honours; II. Advanced; III. Elementary. Grade I. is intended principally for foremen, overlookers, &c.; Grade II. for journeymen; Grade III. for apprentices; but candidates

may enter themselves for any grade they choose. Certificates (first and second class) will be awarded in each grade. Candidates who have taken a certificate may be again examined for one of a higher grade or class in another year.

Any person desiring to be examined may present himself, but before he can take a certificate in technology he will be required to have passed the Science and Art Department examination in certain science subjects. There is no limit of age. Intending candidates should apply to the secretary of the nearest local committee, who will forward their names to the Central Office in London, and through whom all information will be furnished. It is only in the case of candidates failing to make arrangements with the local secretary that any application can be considered by the Central Office.

The examinations are conducted by means of printed papers, and the answers are written upon paper specially provided for the purpose. The papers are sent down in sealed envelopes to the secretary of the local committee immediately before the day of the examination, and the envelope containing the papers is opened by a member of the committee, in the presence of the candidates, on the evening of the examination. A number is allotted to each candidate, and he is known to the examiner only by that number. The worked papers are sealed up at once, and despatched to the office of the Institute. The certificates and prizes will be forwarded to the local secretaries as soon after the examination as possible. No application on the part of any of the candidates is therefore necessary.

The following are the subjects included in the scheme of examinations:—Alkali manufacture, blowpipe analysis (practical), brewing, calico bleaching, dyeing, and printing, carriage building, cloth manufacture, cotton manufacture, electro-metallurgy, gas manufacture, glass manufacture, goldsmiths' and silversmiths' work, iron manufacture, lace manufacture, oils, colours, and varnishes (manufacture of), paper manufacture, PHOTOGRAPHY, pottery and porcelain, printing, silk manufacture, silk dyeing, steel manufacture, sugar manufacture, &c., tanning leather, telegraphy, watchmaking, wool dyeing.

The following prizes will be given in each subject:—Honours—1st prize, £5 and a silver medal; 2nd prize, £5 and a bronze medal; 3rd prize, a bronze medal. Advanced—1st prize, £3 and a silver medal; 2nd prize, £3 and a bronze medal; 3rd prize, a bronze medal. Elementary—1st prize, £2 and a silver medal; 2nd prize, £2 and a bronze medal; 3rd prize, a bronze medal. No first prize will be awarded to any candidate obtaining less than 85 per cent. of the full marks, and no prize to any candidate who does not take a first-class certificate.

I. The examination in Photography will include questions founded on such subjects as the following, but will not necessarily be confined to these subjects:—

1. The characteristic properties of pyroxyline for the manufacture of collodion, and the various substances employed for the purpose, as well as the solvents, such as ether, alcohol, wood naphtha, &c. Different qualities of collodion.

2. The various processes, both wet and dry, including the Daguerreotype; and the principles involved in each. Emulsions, both with collodion and gelatine, paper processes, developers, acid and alkaline, intensifiers, &c.

3. Processes for portrait work, landscape work, copying pictures, maps, engravings, and documents of all kinds. Printing in silver, and other metals, in carbon, Woodbury-type, vitrified enamels; toning, and fixing.

4. Special applications of photography to engraving, typography, photo-lithography, including the various processes for collotype, &c.

5. Special applications of photography to astronomical and microscopical purposes, as well as for recording meteorological and other observations.

6. Lenses and the various purposes for which they are

specially adapted. The construction of cameras, and other apparatus, &c.

II. For the full Technological Certificate, the candidate will be required to have passed at least in the elementary stage of one of the following science subjects:—

8. Acoustics, Light, and Heat.

10. Inorganic Chemistry.

11. Organic Chemistry.

We have given the information, without comment, as it appears in the programme of the Institute; but we must remark, *en passant*, that it is very gratifying to find the ancient and honourable guilds of the City of London abreast with the age in encouraging technical education, the conservation of which was one of the aims of their foundation.

To working photographers these offers hold out especial advantages. There has long existed a feeling in the minds of many to the effect that the status of photography, and the qualifications of photographers, would be greatly elevated if some authoritative examination existed empowered to give certificates of merit. The desire was laudable, and the necessity great; but when its fulfilment seemed most hopeless, here the *deus ex machina* is suddenly presented. We heartily hope that many young photographers will avail themselves of the opportunity, and that the incentives offered will produce earnest and successful students.

There is, by the way, one fact connected with the information which we find we have omitted, and with much pleasure add here, believing it will constitute an additional incentive: the appointed examiner in photography is Captain Abuey, F.R.S.

FRENCH CORRESPONDENCE.*

PHOTOGRAPHING THE NATIVES—GELATINO-BROMIDE DRY PLATES—TRIAL OF DRY PLATES BY PHOTOGRAPHIC EXCURSIONISTS IN NORMANDY—MULTIPLICITY OF FORMULE FOR EMULSIONS—GREAT DEMAND FOR PHOTOGRAPHIC VIEWS OF THE COAST OF NORMANDY.

Photographing the Natives.—As we are on the subject of incidents of a comic character, it would be wrong to omit mentioning one of that kind which occurred the other day at Brussels. In the Zoological Gardens of that city there has now, for some time, been a troupe of Zulus exhibiting. These interesting beings had attracted much notice by their various feats and antics, showing that the *locale* for their exhibition had been selected with admirable appropriateness. The other day the Director of the Gardens was seized with the idea of having the natives photographed, as they were soon about to leave the place. When the Zulus caught sight of the photographic apparatus, their amazement was indescribable; they danced about like creatures possessed. They cried, they laughed, they clapped their hands, and finished by seizing the wide-awake of the unfortunate photographer and wrapping themselves in his focussing cloth, in which costumes they assumed attitudes anything but academic. Suddenly, when the objective was directed at them, and the photographer began to make frantic efforts to induce them to keep quiet for a moment, they became angry and suspicious, and, no doubt taking the instrument that was directed at them for some implement of war, and the supplicatory gestures of the artist for threats, they set to demolish the camera; some seized the dark slides and plate-boxes, others the focussing glass and camera legs. Never was a stranger sight seen; had it been known beforehand that such a scene would take place, many would have paid heavily for a seat to see it. Fortunately for the photographer, a brewer's cart chanced to pass near, on its way to the restaurant of the gardens with a load of bottled beer, and the Zulus, whose excitement was increased on beholding it, at once

threw themselves on this unexpected booty. So they let go the camera and its owner, who, glad enough to escape, swore he would never again attempt to take any specimens of a savage race. As for the Zulus, when they had emptied a number of bottles, they lay down and slept off their drink as if nothing had happened; this was the last stage of this attempt at *Zulugraphy*.

Gelatino-Bromide Dry Plates.—To return, however, to more serious matters which we must not neglect, though there is very little space left. There is just now a great run on dry plates here; every one wants to try them, and it is really time they did so. Several manufacturers of dry plates have sprung up, as if by magic. In addition to those houses already established, whose managers had not been afraid of failure and groping their way, we can now name in France those of Messrs. Garbe and Laisne (the one a chemist, the other a photographer, who have entered into partnership), and of M. Eugene Cheron, an operator well known for his artistic photographs; and in the Netherlands Messrs. Wegner and Mottu, at Amsterdam, who have succeeded in producing first-class plates. It has been asserted in Paris that these gentlemen were only agents for plates imported from England, but this is a mistake, which it is important to rectify; their wares are all their own make, and are all produced at their Amsterdam shops. I cannot refrain from wishing complete success to all these gentlemen who have so courageously undertaken the risk of starting a new industry.

Dry Plates for Tourists.—I send you the following part of my letter from the beautiful country of Normandy—from the very spot where William the Bastard embarked in 1066 for the conquest of England. I have found my way hither in order to join the excursions organised by the *Societe Francaise des Archives Photographiques, Historiques, et Monumentales*, and I am in consequence able to state with very great pleasure that dry plates are at last commencing to make their way among us. Tourist photographers now acknowledge that, for them at all events, there is a rich mine to be worked in the practice of the new process. It is, therefore, easy to understand the enthusiasm with which were received the numerous successful trials made during these excursions. After having examined the principal pictures that were taken, and satisfied themselves of their success, the members of the Society naturally discussed the new process which is destined to completely revolutionise the practice of photography, and in my capacity of a faithful chronicler of events I think it right to lay before you a general resumé of the opinions that were formed.

Multiplicity of Formulæ for Emulsions.—Great complaints were made of the confusion into which one was liable to fall in the preparation of gelatino-bromide emulsions. Every day new formulæ are published, or some one has discovered a better method than that of his neighbour. If I were compelled to prove the real value of every attempt that is brought forward, and to follow all the experiments that are recommended, I should be obliged to pass my time from morning to night in the laboratory, and, after all, I should labour under the disadvantage of being quite unable to say which is the best method of preparing gelatine emulsions. Now this would be running the risk of losing an enormous amount of time, which is much more valuable than the best dry plate ever turned out. Besides, I should be led about from Peter to Paul at the beck and call of every one who professes to have invented something new, and when I had taken the trouble to investigate the so-called invention, I should probably find that it differed only in name from some well known method, which the self-styled inventor had varied in some slight degree by substituting in a formula one product for another possessing the same properties. I think your readers will agree with me that such proceeding as this is more like meddling and muddling; but the same thing will occur again and again so long as we listen to every pushing individual

* Continued from page 451.

whose only object is to bring his own name prominently before the photographic world. Unfortunately, if the real and earnest inquirer suffers himself to be led away by these will-o'-the-wisps, the cause of true scientific investigation cannot but suffer. The truth of these remarks can be established on reference to the transactions of any of our photographic societies. No sooner does one pretended discoverer get up to vaunt the excellence of his own special discovery, than half-a-dozen others rise, not to expose the defects of his process—they are generally too polite to do that—but to declare that they themselves had previously discovered the same, or a similar, thing. It is quite right to accept improvements and to follow them, but it is time to put a stop to this continual production of new formulæ, each of which differs very slightly from others previously published. It calls to mind a number of physicians prescribing for the same malady, each one writing a different prescription, yet knowing that it is no more likely to do the patient any good than his predecessor, and on this account, if on no other, the experience gained during the excursions in Normandy has had the effect of convincing both professional and amateur photographers that their best and simplest way will be to use plates prepared beforehand by some experienced maker. It will, as I have already pointed out, save them an infinity of valuable time and space, and much trouble and vexation. Moreover, the time thus gained will be of great service to them, for the new process requires many artificial arrangements, much special knowledge, and, above all, a very careful manipulation with the camera. M. Letellier, the President of the *Societe Francaise des Archives Photographiques*, insists very strongly on these points, for, as he says, one can only become a smith by knowing how to forge. He has gone further, and attempted to put his views into practice by publishing a little manual of instructions how to work with dry gelatine plates, a careful perusal of which ought to enable a photographer soon to acquire sufficient dexterity to produce results as successful as those obtained by the members of the Society who joined the excursions in Normandy.

Demand for Photographic Views on the Normandy Coast.—Wandering along the picturesque shore of Normandy, among the sites of an infinite variety of historical monuments and works of art, which one is never tired of admiring, contemplating there both the beauties of nature and the masterpieces of human genius, one is led to understand the great sale there is in this privileged country for photographic views and reproductions. Travellers and tourists from all parts of the world, and especially artists, who, equipped with their easels and mahl-sticks, may be met with at every corner, look for them with eagerness and buy them with avidity. Thus our three best landscape photographers—MM. E. Letellier, Neurdein, and A. Davanne—have taken a large number of views which, especially during the season, are sold as soon as they are exhibited. These of M. Davanne have perhaps an advantage in one respect, which is that they are sold at a much lower price.

K. VERSNAEYEN.

MONCKHOVEN'S PHOTOMETER FOR THE STUDIO.

IN his letter published in our issue of the 26th September last, our valued French Correspondent, M. Leon Vidal, mentions a new photometer for the studio, the invention of Dr. Van Monckhoven. We have now received from the Editor of the *Bulletin Belge* Van Monckhoven's own description of the instrument, of which we give a translation below:—

Dissolve 100 grammes of uranium nitrate in 200 grammes of water; pour the solution into a porcelain basin, and heat it over a Bunsen burner; add gradually a hot concentrated solution of ammonium carbonate and

water, when a brisk effervescence, caused by the disengagement of carbonic acid gas, will occur, and a yellow precipitate of uranate of ammonia will be formed. Continue to add the ammonium carbonate, and the precipitate will be redissolved, until the liquid becomes quite clear. This is owing to the uranate being soluble in an excess of ammonium carbonate. Now leave the solution to cool till the next day, and the bottom of the basin will then be found to be covered with crystals of the ammonio-carbonate of uranium; these crystals must be lifted out, placed on a piece of blotting-paper, and dried slowly in a drying oven. Then make a solution of 30 grammes of oxalic acid in 200 grammes of water, put 50 grammes of this salt of uranium into it, and shake the mixture. The uranium salt dissolves with the evolution of carbonic acid, and uranic oxalate is formed; this must be filtered into a flask, A (see fig.), made to hold exactly 250 grammes, and the flask

is then filled up to the neck with water. Into the neck of the flask is fitted an india-rubber cork, B, which is pierced, and carries a tube, C D, about 30 centim. in length. When the cork is pressed down in the neck the liquid rises to the point G; in order that it may do so the lower end of the tube must project a little beyond the bottom of the cork, but not to a greater distance than one or (at the most) two millimetres. The tube must also be furnished with a movable scale on paper, graduated to centimetres and millimetres. If the instrument is to be used as a photometer for the studio the bore of the tube must be one millimetre in diameter, but for the carbon process it should be four millimetres.

As the liquid is affected also by heat, the instrument must be left for some time in the place where it is to be used, in order that it may have the same temperature. To prevent the light from acting on it, it may simply be kept under a cardboard shade. So soon as it is exposed to daylight the liquid will be seen to rise in the tube, and if the light be strong, and the tube (D C) very narrow, it will reach a height of several centimetres in less than a minute.

If the flask have a capacity of half a litre, and the bore of the tube be one millimetre in diameter, the action will be so rapid that the reading may be taken at the end of thirty seconds. As the colour of the solution is rather of a pale green, it may be made stronger by aniline violet, which will enable the liquid to be easier seen in the tube.

The action of the apparatus is as follows:—Under the influence of light the uranic oxalate is converted into the corresponding uranic salt, and a certain quantity of gas is liberated, which accumulates in the upper part of the flask, and causes the liquid to rise in the tube by an amount directly proportional to the action of light. To allow the gas to escape, and the column of liquid in the tube to fall to its ordinary level, it is only necessary to loosen a little the cork, B, in the neck of the flask.

This photometer possesses a very great advantage over those in use among photographers, namely, that it does away with the necessity of comparing different tints in order to read off the degree of photogenic action. If it be kept clean, by pushing an iron wire through the tube from time to time, the instrument will last a long time. In 1840, Draper pointed out that ferric oxalate could be made to serve as a photometer, and at a later period Marchand actually employed that substance with success for the purpose indicated. But the oxalate of uranium is much more sensitive than the corresponding salt of iron, though its use in that capacity has hitherto never been suggested.

"However," as Dr. Monckhoven adds in conclusion, "the question of priority is of no importance. All that I desire to point out is, that photographers can make excellent use of this instrument in the carbon process, and especially for determining the necessary length of exposure in the glass studio."

Correspondence.

A CHEAP INSTANTANEOUS SHUTTER.

SIR,—I think there is no worse policy than that of the various manufacturers of apparatus "laying it on thick," especially in small matters. Notwithstanding the competition in such matters as cameras, if we come to calculate and consider, it will be found the prices charged afford a very fair profit for time and material; but when we go further to require tripod stands, inner frames, extra dark slides, the price asked is unreasonable, and manufacturers and dealers must not be surprised if a co-operative undertaking proves successful, or if the ingenious youth tries to do without superlative luxuries.

A few days ago, I wanted to try an experiment with dry plates which required an absolutely instantaneous exposure, or at least one which would be a mere flash. On enquiry, I found I could not obtain anything like a dark shutter under seven or eight shillings, others mounting up to still higher prices. Now on looking at these apparatus, I thought the price exorbitant, and not being a Cræsus, I had either to give up my idea, or try some other means: and with less than half-an-hour's thought, I had sketched out the plan of a machine which I thought would answer, and which I successfully carried out with (in all) about an hour's labour. The materials were all at hand, and I did not disburse one half-penny. I will therefore proceed to show how my photographic brethren may do the same, and I have no doubt with a little gumption we might save ourselves many a penny, a shilling, and a pound.

I must premise that I had a very quick Grubb's lens, with an outer flange about one-teuth of an inch thick. My first care was to collect from a heap sufficient old postage cards to make two boards of the same thickness; this can be done by gumming or pasting them together, then laying a weight on them and leaving them till next day to get dry. I next trimmed them with a sharp knife and straightedge to the same size; and now in one I cut a circular space, just large enough to receive the flange. Over this, I again fixed two more cards, and made a smaller aperture the size of the opening of the front of the lens.

Another aperture was cut in the second card to receive the body of the lens, and the two were united at one side by a piece of stout linen to open like the covers of a book.

The next thing to do was to cut two strips (off an old quarter-plate) of glass a quarter of an inch each, and two of

Cover.

a little more than three-eighths wide. The narrower of these were cemented on the outside of the cover in the direction

Fig. 2.

a. a. a', and the wider strips upon the other, forming a

groove (Fig. 2) *b b*, an india-rubber ring; *c*, serves to keep it close. The whole, to make a little more presentable, was finished off with orange paper, from the packets of dry plate. I now made out of a strip of thick card the shutter, Fig. 3,

Fig. 3.

which fitted the groove formed by *b b* easily, cutting out a hole *d*, the size of the lens, and covered with black paper from the same source. When the whole was dry and worked well, it was surprising by a quick stroke how brief was the flash of light on the ground glass; but even this I had to reduce by making a second slide, with a small slit instead of a circular opening. Thus, I constructed an admirably working instrument, without extra outlay, and mostly from waste materials.

I would suggest that in cases where a landscape has to be taken, an extra slide be kept with a circular opening; over this might be pasted a piece of black card with three slits thus, which could be improvised on the spot; the object of

the slits is to give a contracted exposure to the sky, and a larger one to the foreground. Other devices will suggest themselves to the minds of the ingenious.—I am, yours obediently,
SOLOMON SMUDGE.

RAPID COLLODION EMULSION.

DEAR SIR,—Whilst everybody is enthusiastically chaunting the praises of gelatine, may I recall for a moment attention to an old and faithful servant of the photographer—collodion?

By your permission I will restate, for the benefit of your readers who may not have seen Mr. Williams's articles in your contemporary, a very simple, rapid, and effective process with collodio-bromide emulsion, briefly adding my own experiences therewith. I will give the process in condensed form from Mr. Williams's two articles, adding remarks of my own, as comparing it with the much-vaunted gelatine process.

To begin, then. Mr. Williams states that rapid emulsion can be made by a permanent excess of silver, corrected by an acid; but that such emulsions change very rapidly, and, in his hands, "wash" very imperfectly—that is, the process of washing seems to remove all properties of giving reasonable density—and, after carefully noting the propensities of permanent excess of silver, he decided to observe the effects of temporary excess, restoring the emulsions afterwards to a condition of excess of bromide. He tried emulsions in which the silver was in excess, some for a very few hours, and others for days, and arrived at the conclusion that a very few hours of excess suffices to produce the change sought for. For the preparation of the plain collodion, Mr. Williams recommends the use of celloidin, though he has no doubt that the formula would work well with any other cotton with, perhaps, some slight variation. The formula for eight ounces of emulsion is as under:

Celloidin (4 grains per ounce of solvents)	32	grs.
Methylated spirit (824)	...	2½ ozs.
Methylated ether (725)	...	4 "

The celloidin should be cut up, and put into a large bottle with the solvents, and the bottle laid on its side so that the celloidin presents as large a surface as possible to the solvents. After about a couple of days, during which it should have a good shake now and then, you will

have a good plain collodion, and the bottle may now be placed upright, when, according to theory, no deposit should take place, as celloidin is a normal cotton, dissolved, filtered, and then evaporated, so that by its use we save, at least, all trouble of filtering or decanting, which, with some samples of high temperature cotton, is a very difficult, troublesome, and wasteful operation.

With regard to the bromides, Mr. Williams states that none gave results (in his hands) equal to the double bromide of cadmium and ammonium, which is easily made by placing in a crucible (porcelain) of (say) six or eight ounces capacity—

Bromide of ammonium	98 grains
Bromide of cadmium	172 ,,

Add a drop or two of water, and liquefaction will take place. Put the crucible over a spirit lamp, and the salts will dissolve and boil, become dry, and then fuse into a solid lump, which should be extracted from the crucible, and powdered in a mortar, and bottled off into a clean, dry bottle, closely corked. The equivalent of the double salt is 117.

Mr. Williams says his deductions carry him to the hard fact that perfect collodion emulsions should require no preservative whatever, especially as any preservative used after coating renders a given film insensitive to a certain degree. A perfect emulsion film must be normal, and, therefore, not liable to change; any organifier or reducing agent in a film lurks there, ever ready to engender a spontaneous change, which may take the form of insensitiveness, or, worse still, that desensitizing or destruction of the impressed image after exposure. These drawbacks can scarcely be urged against soap, because, according to Messrs. Fox, Bolton, and other well-known writers, soap forms an oleate of silver if introduced into the bromised collodion before sensitizing. Glycerine, too, favours openness of films, but washes out, whether the emulsion be used as an unwashed or a washed one. He purchased a bar of glycerine soap, hoping it might be what it purported to be. An alcoholic solution thereof was made, and it is this that will be mentioned in following formulæ.

The celloidin having been dissolved previously as directed, you can rely upon one uniform condition of the plain collodion, and by pouring a quantity thereof into a bottle marked with a scratch corresponding with the amount required, accuracy and uniformity are combined. Having then ready your plain collodion in the quantity above given, add the bromide as under:—

Double bromide of cadmium and ammonium ...	56 grains
Alcohol solution of glycerine soap ...	2 or 3 drms.

When the double bromide is all dissolved, sensitize with—

Silver	125 grains
in	

Methylated spirit	1 ounce
--------------------------	---------

The silver should be dissolved in the smallest quantity possible of water, by heat, in a boiling flask, and the alcohol added in the usual way, reserving a little of the alcohol to rinse out with. Ten hours afterwards, correct with—

Double bromide	30 grains
in	

Methylated spirit	$\frac{1}{2}$ ounce
--------------------------	---------------------

With regard to the sensitizing, a word of caution is added: not to attempt to get the silver in a too concentrated state. A few drops of water and plenty of alcohol will make a solution which will not crystallize in pouring in. It is found by experience that concentrated solution of silver will crystallize the instant it enters the collodion, hence a considerable insoluble precipitate of minute crystals, no doubt enveloped in a skin of bromide of silver; and it is proved to my satisfaction that an emulsion containing much insoluble matter at the bottom of the bottle never works so well as one with little. A few drops of hot water in eight ounces of emulsion can make but little matter. Twelve hours after correcting, if this emulsion

be tried, and if it has not had nitric acid added on the first stage, it is probable it will fog. The experimentalist is advised to use nitric acid in the first batch he makes under this formula—say 2 drops per ounce, or 15 drops to the lot. Afterwards he may risk it without. Mr. Williams states he has tried the effect of adding two drops at a time, trying a plate between each addition, and when clean, leaving it so. He also tried a large ultimate excess of bromide by dropping in bromide of zinc in alcoholic solution at the rate of one grain to each ounce of emulsion. The emulsion is ready for use twenty-four hours after being first compounded. Used unwashed, each plate coated separately, and exposed wet, he has obtained out of doors in diffused light portraits instantaneously, and in varying light an exposure of two to three seconds has been enough and too much.

This emulsion works equally well, either unwashed or washed, though it is doubted if unwashed emulsions would be suitable for the studio.

The following is the plan given for washing. Clean a dish with French chalk, and pour out your emulsion a quarter of an inch deep. Allow it to set in a warm place, and dry by gentle heat until the pellicle leaves the dish in a sheet like chamois leather, and is dry enough to be torn like blotting-paper. Tear the sheet up into pieces an inch or so square, and it will be about right if you can just see through the pellicle. A "bee glass" is recommended as a very good washer. Strain two thicknesses of muslin over the open end, and tie round with string. The hole in the nob allows the pellicle to be put inside, and the water also; but the simplest way is to put the washer in a basin (or jar of water, and souse it up and down. Half a dozen changes of water and one night to soak, will remove all free salts, &c. After washing, lay the pellicle out on a dish to drain, and place on the top of the dark-room lantern or other similar contrivance. Watch matters till you see the pellicle shrivel up and snap readily in the fingers, and are certain that all moisture is removed. Stop the drying. The pellicle is now about the thickness of a wafer, is beautifully white, and retains the polish of the dish. Weigh it, and redissolve at the rate of 20 grains per ounce in equal quantities of absolute alcohol (795) and mythelated ether (725). The resulting emulsion, after twelve hours for solution, is very smooth and creamy, and gives beautiful films, which work well either wet or dry. It requires little or no filtering, merely subsidence, permitting plates to be coated in ten minutes after shaking up, and it will be found that the emulsion remains creamy with very little separation.

Great care is urged in the drying both of the first emulsion and the washed pellicle, and care must be taken not to over-heat either. If the emulsion be dried to a tough skin in the dish by heat it may be known to be ready; when if a sharp paper knife be run round one corner, it splits off with a smart crack, and shrinks to about half the size of the dish; it can then be torn up and washed without fear of losing half of it in the process. This emulsion washes well, gives cleaner pictures after washing than before, and the difference in sensitiveness is hardly appreciable. With regard to development, Mr. Williams states that after dozens of plates prepared with this emulsion he finds nothing so satisfactory as ferrous oxalate, as fog is apt to show itself with alkaline pyro. "Under ferrous oxalate," he says, "no such naughty propensities are visible; the plates develop perfectly clean, and, what is of vital importance, there is a clear gain of twenty-five per cent. in the exposure." Now, for myself, I have never tried ferrous oxalate, as the only plates I have tried with this emulsion I developed by alkaline pyro; but from what I have seen and heard regarding ferrous oxalate, I should judge it to be all that is claimed for it—simple, certain, and producing full printing density at once if the exposure be correct.

An amateur friend of mine who had no previous experi-

ence in photography, save and except that which was to be obtained from a sixpenny manual of the wet collodion process, and with a cheap set of apparatus, such as can be obtained for about £3 or £3 10s., determined to try some of this emulsion, and did so, meeting with such success that he has quite abandoned wet collodion. I may say that, although only an amateur, he is a most careful and precise manipulator, and to that I attribute a great part of his success. Indeed, I have no doubt that anyone, with care and precision in his manipulation, could work these plates with complete success. I tried about a dozen plates prepared with some emulsion of my friend's make, developing them with alkaline pyro, and although, as has been mentioned, they showed a slight propensity to fog, they were in all other respects excellent. But those developed by my friend with ferrous oxalate showed no signs of fogging whatever, and came up to full printing density in a few seconds, besides being beautifully soft and full of detail.

As regards the exposures, it is a real treat to work with such plates. I tried several with a common quarter-plate lens belonging to my friend's cheap set of apparatus before mentioned, and obtained portraits out of doors instantaneously, and one or two in ordinary sitting rooms, on a cloudy day in fifteen to twenty seconds, while in a well-lighted glass-house I got portraits in two to five seconds.

This, I think, ought to be rapid enough for anybody, whilst the saving in time, trouble, and expense gives these plates an immense advantage over the bath process and the costly and troublesome gelatine plates. To quote Mr. Williams's own words:—"Coating a plate with a washed emulsion and placing it in the dark slides as soon as set is a process at once most economical of precious time, and facile as regards its almost amusing simplicity, and I feel convinced that if portraitists would take the matter up and introduce quick washed emulsions into their studios, they would find a wonderful advantage accrue."

I now leave this process to speak for itself, hoping that some of your many practical correspondents will try it for themselves, and give us the result of their experiences.—I am, sir, yours &c.,

COLLODIO-BROMIDE.

LUXOGRAPH PICTURES AT FALMOUTH.

SIR,—Referring to the correspondence which has of late appeared in your pages, I am now in a position to explain matters. I refrained from doing so until I had heard from the Falmouth Polytechnic authorities. I have this day received a letter from the Secretary, together with the correspondence that has taken place both with the Luxograph Company and Mr. Hazard, and at the request of the judges I have the pleasure of informing you that at a special meeting Mr. Hazard has been awarded a first bronze medal for his series of portraits taken at a fancy dress ball. The Luxograph Company have given a full explanation, saying they did exhibit some of Mr. Hazard's productions merely to show the capabilities of the apparatus. I myself think if the Company at the time had made a statement, this unpleasantness would not have occurred, and I also think they were in error to exhibit another person's work without giving notice both to the artist and also to the Society, as they must be well aware that the judges take for granted, and in good faith, that the exhibits sent are the productions of the exhibitor, unless otherwise stated, and are dealt with accordingly; and as several of the pictures arise from the same negative, it was impossible for the judges to decide in the matter. I am very pleased that it has been settled, and, I hope, to the satisfaction of all parties.—Yours very truly,

W. BARKS.

MEDALS AT FALMOUTH.

DEAR SIR,—It was not to be supposed that my last letter would be gratifying to Mr. Cocking; but I beg to

assure him that it was not in any way intended as a disparagement of his ability, or to show that he was the first (by a great many) who had placed his name on work not actually his own execution, and obtained a medal for it. My only object was to endeavour to find out upon what principle medals are awarded.

If Mr. Cocking obtains as many medals as will cover the dome of St. Paul's, it will not make the slightest difference to me; and the fact of the Society of Great Britain having awarded a medal last year under similar (?) circumstances does not alter the case now under discussion. "Any number of wrongs will not make one right."

My letter is not in any way a "breach of confidence." I heard the facts I mentioned quite publicly, and not from any one in connection with either of the firms alluded to in my last. I would, however, remind Mr. Cocking that had the picture been labelled "An Enlargement in Carbon by the Autotype Company, from a negative by H. G. Cocking," a "breach of confidence," as he calls it, would have been impossible.

If not too late, let Mr. Cocking send a print from the negative actually taken by him, to the Society's Exhibition about to be held, and I wish him success.

I may not be able to visit the Pall Mall collection, but I shall watch the list of awards with interest.

NOT AN EXHIBITOR.

RECOVERING SILVER.

SIR,—I would be thankful to know the experience of any of your readers in recovering the silver from a cyanide negative dip bath. I think the result should be a financial success.

OLD MAN.

[We presume our correspondent means a cyanide fixing-bath. Evaporating to dryness, and reducing the residue with due proportion of flux in a crucible, will give him metallic silver. The operation would require great care.—Ed.]

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Association was held on Thursday evening, the 25th ultimo, in the Lecture Room of the Free Library, William Brown Street, Mr. J. H. T. ELLERBECK, Vice-President, in the chair.

The minutes of the preceding meeting were read and passed. Mr. R. HOULGRAVE passed round a number of very excellent negatives and prints from them. The negatives were prepared by Captain Abney's gelatine emulsion. He (Mr. Houlgrave) strongly recommended the process, especially to those whose time was limited, as he was able to make the emulsion and coat a dozen plates in an hour and a-half. They were not so sensitive as they would be with a prolonged cooking; but he did not care to be obliged to develop in a very non-actinic light.

Mr. W. H. KIRKBY also spoke of his success with Captain Abney's process. He generally cooked the emulsion thirty-six hours. He had tried ninety-six hours, but then found the films frill badly under development.

Mr. HOULGRAVE described his methods of filtering, and explained that a conical piece of sponge—not pressed into the neck of the funnel, but pulled in by means of a thread near the point of the cone—was far better than any other method. It could be used again and again after washing; and, if employed for collodion emulsion, he rinsed the sponge in ether and alcohol. Cotton wool could also be effectively used in the same way by pulling into the neck of the funnel with a thread, and afterwards drawing the thread away.

Mr. W. E. POTTER exhibited a rapid shutter, which was exceedingly portable and effective, as the beautiful pictures taken by its means testified. A whole-plate view of the mouth of the Mersey from New Brighton Pier, with numerous vessels leaving the port, and one of the Isle of Man steamers passing the pier at full speed, were particularly admired. The shutter was, at the suggestion of Mr. Kirkby, placed between the lens—in this instance a Ross's doublet—and consists of a brass plate about four inches in diameter shaped a little larger than

a half-circle to leave room for a pivot hole in the centre. The shutter is just the thickness of the stops, and fits into the stop slit, which, however, has to be cut deeper to allow the shutter to revolve. A pin, round which is wound a spring wire the end of which projects at right angles, is passed through the centre hole of the shutter, and slips with its octagonal end into an octagonal socket fastened to the outside of the lens tube. By drawing round the shutter until closed the end of the spring wire presses on a knob of the shutter, which is fixed by a little catch. On this being released by pulling with a string the shutter rapidly revolves, bringing its opening—which is of an oval shape and cut in the centre of the shutter—past the opening of the lens. The octagonal-ended pin which holds the shutter in its place enables the operator to vary the length of his exposure, by fixing the spring to work strong or weak by turning the pin an eight or quarter round. The shutter can be taken off in a moment, and the lens can be used in the ordinary manner.

Mr. B. BOOTHROYD showed some specimens of platinum printing and explained the process.

A number of prints were exhibited by the Rev. H. J. Palmer, Mr. T. W. Bruce, Mr. Potter, and others, and Mr. J. A. Forrest exhibited a capital view of a rocky promontory on the coast of Wales, which he had taken from a steamer going past at full speed.

The meeting was shortly afterwards adjourned until the 30th instant.

A PHOTOGRAPHIC CLUB.

At a meeting of photographers held at the rooms of Mr. Brittlebank on the 1st day of October, 1879, Mr. A. L. HENDERSON in the chair,

It was proposed by Mr. CUTCHEY, seconded by Mr. MAWDSLEY, and carried unanimously—"That in the opinion of this meeting it is desirable that a Photographic Club be formed."

It was proposed by Mr. FOXLEE, seconded by Mr. COWAN—"That no one be eligible for membership unless he be a member of a photographic society."

It was proposed as an amendment by Mr. PAYNE JENNINGS, seconded by Mr. LAWRIE:—"That though advisable that the members of the Club should be members of a society, such be not imperative."

It was further proposed, as a further amendment, by Mr. BOLTON, seconded by Mr. PEARSAL:—"That anyone (photographers or otherwise) be eligible to be members."

Upon a show of hands the proposition of Mr. Foxlee was carried.

It was proposed by Mr. FOXLEE, seconded by Mr. MAWDSLEY, and carried—"That a Committee be formed to carry out the preliminary arrangements, such Committee to consist of nine gentlemen, five to form a quorum."

Committee.—Messrs. Henderson, Bolton, Cowan, Payne Jennings, Brittlebank, Foxlee, Dunmore, Mawdsley, and Cutchey.

Mr. BOLTON proposed, and Mr. COWAN seconded:—"That the resolutions passed at this meeting be subject to such modification as may seem desirable by the Committee; such modification to be submitted to a General Meeting."

Talk in the Studio.

CENTREING A LENS.—For many purposes it makes little or no difference whether the axis of a lens corresponds with its geometrical centre; but for telescopes, opera glasses, photographic cameras, and other instruments of accuracy, their optical and geometrical centres must correspond. In testing lenses to ascertain if the optical centre and the geometrical centre coincide, the lens is cemented to a chuck upon one end of a hollow lath mandrel; near the opposite end there is a ground glass surface, and in front of the lens being tested, there is another lens supported on a standard, beyond which there is a small vertical rod and a lamp. These different pieces are all in line with the axial line of the mandrel, and an image of the rod is cast upon the ground glass screen. If the image remains stationary while the lath revolves, the optical centre of the lens coincides with the centre of rotation; but if the image moves, the optical centre is out, and the lens must be centred while the cement which supports it is still warm and soft. This is easily done by holding the hands against the

edge and sides of the lens as it revolves. When the lens is optically centred, if its periphery is out, it must be ground down. This is readily done by placing under it a piece of sheet iron bent into semicircular shape, and forced upward against the edge of the lens by means of a screw passing through a board that supports it. The sheet iron is charged with sand or emery and water, and as the lath revolves the lens rapidly assumes a circular form.—*Scientific American.*

SODIUM HYPOSULPHITE IN ERYSIPELAS.—The recommendation of this remedy as a specific against erysipelas is a matter of periodical occurrence. The latest appears from a photographer who writes to *Anthony's Bulletin* that he has derived much benefit from it in his own person, and has personal knowledge of its value in not less fifty other cases. A saturated solution of the hyposulphite in water, of which a teaspoon to a tablespoonful taken every one or two hours is the best form in which to use it internally, while externally equal parts of the solution and glycerine should be applied by means of cotton flannel. Avoid stimulants, and eat farinaceous food only. After the doses above mentioned have been continued for twelve hours, they may be reduced to about one-third the frequency. A moderate amount of purgation does not warrant the stoppage of the remedy.

To Correspondents.

VICTORIAN AMATEUR.—There is, unfortunately, no substitute for light in photography, hence a "remedy for insufficient light" can only be found in securing more light. If, as we infer from your letter, your studio has its glass side 4 feet 6 inches from another building, it is tolerably certain that you cannot have much light of photographic value for your sitters. Such a position is comparatively useless. Have you a glass roof? Can you raise the studio about 10 feet or more, say, so as to bring it within range of more light? In any case, you can whitewash the wall which is opposite your slide-light. It is possible that some of these expedients may improve matters; but it is probable that removing the studio to another and more open position will be the only effectual remedy. 2. A moment's reflection will satisfy you that we cannot with propriety recommend in these columns the goods of any particular manufacturer. There is, however, no need for this. In the early days of the collodion process, when the manufacture of collodion was but little understood, the production of certain manufacturers was often better than that of their less experienced brethren; but now you are safe with almost any of the well-known commercial samples. Of course there is difference in quality, and some operators prefer one, and some another, but all are good. 3. Your question as to the best and easiest mode of intensifying a negative is not quite so easily disposed of. As a rule, it is the practice of good workers in the present day not to intensify at all. If things are working well, and the exposure is right, it is easy, as a rule, to obtain a negative which requires no intensification, sufficient vigour being obtained with the ordinary development. If a negative requires intensifying, the best and easiest mode of effecting it must depend upon circumstances. It is necessary to enquire how much treatment it requires: whether it is over-exposed, or under exposed, or slightly fogged, or clean. Presuming it to be an ordinary negative, with no especial fault but a little want of vigour, then a very simple plan consists in adding a few drops of a 20-grain solution of nitrate of silver, and at the same time a few drops of a 20-grain solution of citric acid to the ordinary developer, and applying the mixture to the negative for a few seconds. Or the old pyro and silver method answers well. Applying a solution of sulphide of potassium will give greater intensity still. But you are doubtless familiar with the many intensifying formulæ we have published in these columns and in the various YEAR-BOOKS. The best to apply depends always upon circumstances, for which no general rule can be laid down.

CAPTAIN TURTON.—We regret that we do not know to what you refer in the note handed to us by the publisher. We do not remember any allusion in the NEWS of Sept. 19th to paper negative plates. Will you kindly refer us more fully to the special reference meant?

A. W. R., Croydon.—We shall look with interest for the pictures. **A SPECIMEN OF PERMANENT PRINTING.**—The curious thing you enclose is apparently half a coloured picture. It is the colour backing to which a transparent photograph is intended to be.

SUBSCRIBER (Runcorn).—The paragraph to which you refer was, as you see, copied from a foreign journal, and so far as we know the process is not patented. But we cannot say with certainty that it is not. The only mode of ascertaining this with certainty consists on a careful search of the records at the Patent Office in Southampton Buildings.

F. GUTKUNST.—Many thanks, received. Some remarks shortly. Several correspondents in our next.

The Photographic News, October 10, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

AMATEUR PHOTOGRAPHY AND LANTERN TRANSPARENCIES— THE TEST OF PHOTOGRAPHIC PROFICIENCY.

Amateur Photography and Lantern Transparencies.—Those of our readers who employ the camera as a pastime and during moments of sweet leisure, should not forget one special application of their work. We mean the preparation of transparencies from their negatives for exhibition in the lantern. Many lady and gentlemen amateurs are perfectly cognisant of this charming application of their work, and we have, indeed, to thank one of their number, a tourist photographer, for a delightful entertainment at which we assisted some ten days ago, when he passed in review a series of plates taken during a holiday tour this summer. We cannot, all of us, hope to rival Mr. York in his production of lantern slides; but those who would desire to know how far perfection may be reached in this branch of photography will do well to inspect that gentleman's clever work. Mr. York goes about the matter in a systematic way, and arranges his series of photographs into "Readings," one "Reading" constituting an evening's entertainment, to make which more complete, he compiles a short descriptive lecture, that introduces the plates one after another as they appear to the audience. Our tourist friend's exhibition of which we have spoken was naturally a more modest affair, but it gave a pictorial account of his ramble with three companions through Yorkshire and the lake district. His pictures were of cabinet size, and therefore full large for the sciopicon in which they were exhibited, and the show commenced by a series of portraits—those of the pedestrians who made the tour—which were introduced with some humour. Mr. Jenkins in his walking costume, Mr. Jenkins in his state costume, Mr. Jenkins' face (enlarged), Mr. Jenkins' back (this ornamented by a huge knapsack and bent with travel), were some of the introductory sketches to the journey. Then we were treated with a group by the wayside, buckling on their knapsacks, and evidently "going to begin," after which the views commenced in good earnest. The first, we remember, was a Yorkshire lane, the massive foliage overhanging the road, in the vista, the backs of three pedestrians on the tramp. Then we get a view of Leyburn and "the Shawl;" of the waterfall at Hawes; of Kettlewell; of Richmond Hill (on which a lass once lived); of High Street, which is not a street at all, it seems, but a ridge some two thousand feet high; of Ullswater, the English Lucerne; and farther on Patterdale, Helvellyn, the Catbells near Keswick, and other spots. We do not mean to say that our friend's pictures were all perfect—far from it. But of this we are certain, that they looked much better enlarged in the lantern than they did printed upon albumenized paper. And here we may remark to our amateur readers not to be discouraged if their plates are not everything that can be wished. They will make very good transparencies nevertheless; and let us add that a photograph, whatever its merits, never looks better than when viewed as a transparency. There are frequently delicate gradations and details which are altogether invisible until the plate is viewed by transmitted light. The amusement and entertainment lantern transparencies afford, especially when taken by the exhibitor, are endless on cold dark evenings, and their inspection does not tire or fatigue, like looking into a stereoscope. As to a lantern, there have been directions given in these columns many a time; you may always make use of your photographic lens, and the rest is not very expensive. The sciopicon, with which many of our readers are familiar, is a very convenient lantern, and, provided with a double wick, gives an exceedingly bright light. We see that Browning, of the Strand, is actually manufacturing a lantern to burn with three wicks, which

is no doubt, more powerful still. As to the preparation of transparencies, that is not very difficult with aid of dry plates. The gelatine films purchased of Swan or other well known manufacturers are exceedingly convenient for the purpose, and will give a transparency by being placed face to face with the negative, and exposed to the light of an ordinary gas flame for a couple of minutes. Sometimes, it is true, the film formed by a deposit of silver is rather opaque, and the light of the lantern has a difficulty in penetrating, and for this reason we ourselves prefer to make our lantern transparencies with carbon tissue. Nothing can be more simple than the production of carbon pictures in this way upon glass. A piece of tissue is printed—we prefer a dark violet—under the negative. The printing must be vigorous, for the gelatine film is very delicate compared to silver, and, after the tissue has been soaked in cold water, it is put, face downwards, upon the glass that is to constitute the slide, and developed. By making a pencil mark upon the tissue, it is easy to fit the same properly upon the glass, but the latter should be rather larger than necessary, so that it may be cut down afterwards if the print has not been developed altogether in its proper position upon the surface. There is no need to be a carbon printer to effect the matter. Supposing you know nothing of printing upon tissue, it is only a question of wasting a few pieces in trying. When the tissue has been sensitized and dried, it is put in a pressure frame in the ordinary way; after sufficient printing (you will ascertain proper time for printing after one essay) the bit of tissue is put for a minute to soak in cold water; taken out, it is clapped, face downwards, upon the glass slide, and after pressing for five minutes under a blotting-pad, if you have not a proper squeegee, immerse the glass plate in warm water at about 90° F., and develop. When the print has been absolved from all superfluous pigment, the glass slide to which it adheres is put into cold water, and the transparency is finished. The veriest tyro will produce a good lantern slide in this way after a couple of trials, but the printing must be deep, and a suitable tint of tissue employed. The pigment sticks firm enough to the glass, but you may varnish if you like.

The Test of Photographic Proficiency.—The examinations in photography that are to be instituted in connection with the City guilds remind one that such examinations are not altogether novel. In connection with the Society of Arts, students may be examined in photography; and at the Staff College at Sandhurst, as also in certain examinations of the Civil Service—to wit, in the case of aspirants for employment in the Royal Observatory—tests are applied to gauge one's knowledge of camera work. Among staff officers a knowledge of photography is very valuable, and hence it is a subject in which many qualify, while the circumstance that various observations are now automatically registered by photography in our observatories renders it incumbent on astronomers to be conversant with the practice of the camera. But examinations in photography, to be really of value, should, we are of opinion, include a practical demonstration on the part of the student, for an examiner could scarcely certify that a man was well versed in the art of photography unless the former possessed some practical proof of the student's manipulating proficiency.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER VI.

HOWIE'S PONY AND MY FISH—RUSSET—AN ITALIAN WITH A SCOTCH ACCENT.

ENOUGH of Iceland! If I liked, I could spin it out for weeks and months; but my readers, I dare say, wish to know some of my experiences since that eventful voyage. I could tell you about wandering over that sterile country

—I could tell you how wearied we got of the uniform scenery—how Jan wakened up one morning, and discovered his dog spotted all over and lined very neatly a *la zebra*!—how he rubbed his eyes—cried, “Mein hund? Wo est mein hund?” and as the poor innocent trotted up to him at the cry, he yelled, “Ho! ho! you beast! you dare come near me when I cry on my dear Slokos—never!” And I can assure you Jan stoned the poor dog, under the impression that he was a stranger and a thief, for a week, when the silver began to wear off. I could tell you how the noble company sickened of the whole job!—how they all gathered together and steamed away for Scotland, very well disgusted with the expedition, only I would have to mention day and date, and I don't wish to do that; it is enough for me to tell that we had to ship in a schooner for Leith—that I occupied and paid for a space, three feet square, to store dried fish—that I filled the same space with fish—that Howie, wishing to do a nice thing to his uncle the horse dealer, bought a pony and a berth for it on board the *Rose*—that we experienced some awful weather! Three times we sighted the coasts of Norway! We *should* have been on the Scottish coast within six days after leaving Reikiavik, and we were *three and twenty!* About the fourteenth day the provant that Tom had taken on board for his pony got exhausted.

“Look here, Geo’,” he cried one morning; “my pony is starving!”

“Can't help it, Tom.”

“Oh, yes, you can.”

“How?”

“Let me have your kippered salmon? I'll give you the same money as you gave in Iceland.”

“That isn't fair, Tom!” I explained; “you should not speak that way. Don't you think that I am entitled to the price I would receive for them in Scotland?”

“Case of necessity, my boy,” explained Tom. “We may never see Scotland! My pony must have food. If you don't give, I shall take!”

“If you do, you do it without my consent; and if you touch a hair of my kippers' heads, your blood be on *your* own head!”

However, Tom took my fish, and, what is more, his pony ate it! Dear old Tom! I could not help being angry and savage with him. I had all my selfish little plans laid: how I was to dispose of the fish, and had even (mercenary wretch that I was!) calculated the probable returns I should receive—the invitations to Sundays and Christmas dinners—a week's board and lodging gratis in the autumn, and innumerable little tokens of love and affection in the shape of handkerchiefs, ties, &c.; and here was a brute of a horse devouring the “open sesame!”

You should have seen us during the time that the fish lasted. We would scramble on deck once or twice during the day, and while I clutched the weather side of the bulwarks, Tom would throw his arms round the gear about the mainmast, and then we would scowl at each other in the most awful manner.

However, there came an end to the fish, and shortly after there came an end to the horse. Tom tried to feed it upon old canvas and ropes' ends, but it wouldn't do. The change was too much from the beautiful kippers it had been used to, and so it—died! Now, don't you think it was particularly mean in Howie to say that he believed it would have lived if it had not been for my fish?

Sick of each other's company, and heartily sick of the sea, we at length landed at the shore of Leith; and, by heavens! I swear it is the dirtiest, filthiest shore ever I landed at! I was wrecked in the *Stanley* ss., about twelve years ago, on the “Black Middens” of North Shields, and have wandered around the Low Lights, and along the low street of that mucky hole; but I must honestly say that Leith—the shore of Leith—for outright filth, carries the palm. For muck and effluvia I'll back it against creation.

In the spring of the following year I engaged with a

man in Newcastle. We will call him Russet. He was the type of a class that I have often met since. He laboured under the impression that every man should be his own wright, carpenter, builder—everything, in fact. The dark room had the appearance of a joiner's shop; it was hung all round with saws and hammers; the corners of the shelves were stuck full of brown paper twists containing nails and screws. You would hardly ever find Russet without a saw or hammer in his hand. The neighbours always knew when he was at home. Had he been a spirit medium of the first water, his presence could not have been accompanied by more noises. He was stripped to his shirt and trousers when I made my appearance in his glass house, and was busy setting up a frame for a background. “How do?—how do?” he cried, as he gave me a sticky hand to shake. “Can you do anything at this? Do you like a bit of carpentering?” He seemed awfully disappointed when I replied in the negative.

“Every one should be able to drive a nail,” he ejaculated.

I quite agreed with him there, and had little doubt but that I could accomplish that feat.

He seemed to cheer up at this, nodded his head approvingly, and treated me to a homily upon the advantages of being able to do a bit of carpentering yourself.

“Look at the expense it saves!” he cried, as he wheeled round his frame and knocked a stucco image off its perch, smashing it to pieces. I don't exaggerate this incident, for if the whole truth was told it would be found that there were two images broken on that occasion; it would likewise be found that they cost Russet seven-and-sixpence a-piece, and had he got a practical man to make the frame it would not have cost over four shillings. “But look at the expense it saves, my boy!”

After Russet had swept away the remains of the images, muttering something the while, not loud, but deep, he turned upon me abruptly, and demanded, “Do you drink?”

Now as I had just been thinking that a glass of beer would be the very thing to help a certain sinking I felt in the inward man, and at the moment I had a very vivid recollection of Ballarat and his developer, I replied modestly in the affirmative.

“Ah, my boy!” was Russet's unexpected reply, “I have not tasted a drop of anything stronger than water these five-and-twenty years, and look at *me!*”

Now when you know that I was a strong, healthy man, weighing at that time some thirteen stone, and that Russet was a puny little mite that I could very nearly put in my pocket, the reader will see the absurdity of his remark.

There was a funny incident occurred while I was in Russet's employment. You must know that the operator he had before me was an Italian. He had communicated with Russet by letter written in the purest English. He had been in Berlin, Paris, and had worked for the famous Claudet; so Russet, thinking to make him a wonderful attraction to his studio, had a few thousand circulars printed ringing his praises, and lo! when the Italian appeared on the scene, never a word of English could he speak. Some interpreters in London had written the letters. Of course there was a row, and the consequence was that the Italian was discharged, and I reigned in his stead.

“And what on earth will you do with all these circulars?” I asked Russet, after he explained the circumstances.

“You can be the Italian!” was his prompt answer. “You are as black as he was, and a little better looking.”

So, although I did not like the idea, I had to submit, and be styled Signor for the first and last time in my life.

A few weeks after I had been with Russet, I had occasion to quarrel with my landlord about some collars that had gone a-missing at the wash; and those who know me best tell me that when I lose my temper or speak

earnestly there is a very palpable Scotch accent to be detected in my tones. So thus, when I had thumped the table and spoke my mind freely—very freely—what were my feelings, do you imagine, when I heard an onlooker who had been listening to me with the utmost attention, exclaim to his comrades: "Well, he may be an Italian, but he is the first I ever heard speak broad Scotch!"

(To be continued.)

THE PRESS AND THE EXHIBITION.

[From the DAILY TELEGRAPH].

VISITORS to the Exhibition, which is opened to-day by the Photographic Society of Great Britain, at the Gallery of the Society of Painters in Water Colours, will not fail to observe the rapid development of processes which, but a few years ago, were unheard of. Apart from its curious and instructive character, in this respect, the display, taken all round, is a decidedly good one, with many points of extraordinary merit. Instantaneous photography, by the use of gelatine plates, is chiefly exemplified by Colonel H. Stuart Wortley, Mr. Joseph Gale, Mr. S. G. Payne, and Mr. Payne Jennings. The first-named of these zealous experimentalists has contributed a remarkable collection of what are in reality sun pictures, though the effect is that of moonlight, with its reflections on cloud and wave. Breezy weather with storm-racked skies is the characteristic aspect in which this accomplished amateur has presented several coast scenes of wild Cornish beauty. "The Dogs of Scilly and their Prey" is the title of one that figures forth a wreck on the outlying rocks of Tresco or Bryher, in which dangerous locality the *Schiller* was lost between four and five years ago. There can be no misconception as to the instantaneous character of Colonel Stuart Wortley's admirable carbon prints. Every wrinkled wave is sharp and clear in its delineation; and the moment in which the spray comes dashing over the savage rocks is happily caught in more than one instance. The honest force and truth of these coast studies, which hang in the centre of the wall opposite the entrance to the gallery, will command universal admiration. Varying the carbon process on which Colonel Stuart Wortley relies for his effects and for their durability, and substituting for his colouring matter smalt or some other enamel pigment, capable of being fused on porcelain, the Autotype Company makes a prominent display, at the upper end of the room, with a number of earthenware or china plaques, on which the photographs have been burnt in. Though not absolutely new, this kind of work is a long way in advance of what has ever been done before, and the size of the enamels has completely taken by surprise the most experienced photographers. It must, however, be confessed that largeness of portraiture, on some of these porcelain grounds, has been attained at a certain sacrifice of refinement and tone. Let them be compared with the truly excellent printing in platinotype, by Messrs. W. Cobb and Son, from the negatives of various hands, and it will be seen where the enamel photographs fall away in soundness and delicacy. Still, as a promise of finer work to come, these pictures are well worthy the attention which their very appearance will ensure for them. The large centre picture of Stoke Pogis Church, the scene, as is generally supposed, of Grey's "Elegy," which piece of landscape photography is exhibited at the opposite end of the room, having been printed and enlarged from a negative by Mr. Vernon Heath, is another of the noteworthy specimens from the laboratory of the Autotype Company. Rivalling it in quality, as well as in size, are two enlargements by the Woodbury Company, from negatives taken by Captain C. H. Verney, in the picturesque neighbourhood of Pain's Hill, Cobham. Portraiture is abundantly represented, pleasing subjects and skilful manipulation sufficing to attract where popular interest is wanting. There are, however, more than two or three heads recognizable as the likenesses of notable persons. The Woodbury Company's enlargement, from a photograph by Messrs. Lock and Whitfield, of Professor Huxley, is one of these, if not, in fact, the chief. Then there is an exceedingly beautiful series of autotypes, in a pinkish red tint, similar to that of the most dainty of Bartolozzi's engravings, the subjects being the young Princesses Victoria, Maud, and Louise of Wales. They will be found at the lower end of the room, under the large picture of Stoke Pogis Church. Signor A. Lombardi exhibits six or seven noteworthy pieces of portraiture, in his best style of finish. Two of these pictures are likenesses of Lady

Gilford, differently posed, but confirming one another in close fidelity to the original. A likeness of Mrs. H. V. Macdonia is another of the Lombardi series; and a strikingly good portrait of Mr. Biddulph is a fourth. Best of all the Italian photographer's portraits, however, is the vivid and thoroughly characteristic head of Mr. Charles Reade. M. Boucher, of the King's Road, Brighton, exhibits a half-dozen of spirited portraits, direct from life, and artistically endowed, in some instances, with a pictorial character. They are grouped in one large frame, and, thus displayed, they conspicuously adorn the right-hand corner of the lower end of the gallery. The subjects are "The Aga's Favourite," "From Erin's Green Isle," "Resting," two portraits of ladies, and one of Major-General Cameron Shute, C.B., M.P., which is distinguished by life-like expression as well as exactness of feature. A single contribution by Mr. T. G. Hemery is a telling portrait of Mr. Glaisher, taken with a platinum base on Whatman's drawing-paper. Heads of Professor Rainy and Mr. Lawrence Hill, both such subjects as Mr. Oules—*who, by-the-bye, is one of the judges of the Exhibition*—would delight in painting, are shown by Messrs. Thomas and Robert Annan. Enamel photography, as applied to portraiture, is well represented in Messrs. Cobb's likeness of the lamented Prince Imperial, and Mr. H. N. White's portrait of the late Mr. Samuel Phelps. Animal painting has a handmaid in photography, as is sufficiently shown by Mr. T. J. Dixon's "Studies of Lion and Lioness," Mr. F. York's carnivora, from the Zoological Gardens, and the instantaneous pictures, by Mr. W. Wainwright, jun., of cows and pigs. The animal forms, also, in those beautifully perfect landscapes by Mr. S. G. Payne, are conclusive evidence that the work is instantaneous. Of this difficult operation, the extremely delicate sea pieces, "Brixham Trawlers," and the various landscapes and views on the Mole, with which Mr. Joseph Gale has ornamented the wall where the numbers corresponding with those in the catalogue commence, are highly meritorious examples. So, likewise, are the patiently-watched moments of natural study, embodied in the English and Irish scenery which Mr. Payne Jennings could only have caught in transient passages of light and atmosphere. When we come to pictorial photography, of the class which involves artificial arrangement, we find, as usual, much that mars perfection. A long practice in this department has taught Mr. Robinson the value of simplicity; and his attempt at *chiar'oscuro*, "Between the Lights," is, perhaps, as successful as any picture of the Josef Israel kind ever essayed by photographic means. But no painter would have been satisfied to allow such accidents as the excess of light on the girl's apron, for instance, to remain. Some rather attractive examples of pictorial treatment come from Chicago, the artist being Mr. H. Rocher; but, despite the eulogy lavished on them, they are certainly disfigured by a blackness which seems to be the result of too long an exposure. After all, there is nothing of the *tableau* kind in this gallery which will for a moment compare with two little works that are very likely to escape notice altogether; though, as examples of printing from combined negatives, they are simply marvellous, and are, in all respects, perfect pictures of the Meissonier type. One is "Henry Kirke White in his Study," and the other "Washing Day," the artist of both being Mr. A. Diston. Scarcely within the category are the four prints which the Autotype Company has exhibited as specimens of Mr. R. Elmore's new work, "Liber Nature," these having been painted by the artist in monochrome, expressly for reproduction, as are the drawings, "Homer" and "Shakspeare," by Mr. F. Madox Brown. Among the special attractions of the gallery are the views taken during the Anglo-Dutch Arctic Expedition of 1873, by Mr. W. J. Grant, a Devonshire gentleman who has made the photography of Polar exploration his favourite study; and the Russian photographs of Brandel and others exhibited by Leon Warnerke of interiors at Warsaw and of scenes in Armenia. The last-named contributor has supplied a number of valuable studies, by Nikitin, of Armenian life and incidents of the Russo-Turkish campaign.

[From the DAILY NEWS.]

THE annual exhibition arranged by the Photographic Society of Great Britain was opened on Saturday, at the Gallery of the Society of Painters in Water Colours, 5A, Pall Mall East. Photography being at present in a transition state, it was for some time feared that the exhibition, in point of size at least, would fall short of its immediate predecessors. This fear has, however, been agreeably disappointed, 404 specimens having been sent in by 93 contributors, of whom 35 are members of the

Society. For two or three years experiments have been going on with the object of substituting gelatine plates for collodion, and thus taking likenesses instantly instead of spending perhaps thirty seconds on the operation. A gentleman named Charles Bennett has at length perfected the new process, saving that a little difficulty in its management is still felt. By using gelatine plates a photograph can during summer be taken in a sixth part, and during winter in a twentieth part, of the time required for collodion; and the art may therefore be said to have passed into a stage in which the possibilities of fixing in black and white the fleeting expressions and positions of man and nature are boundless. The many whose features assume a sullen or meaningless look under the influence of a camera, the parents whose babies refuse to be still when awake, and the photographer who loves to see his pictures instinct with the forms of flying birds, the ripples on the water, and the scudding clouds, will all welcome the new improvement. It could hardly be expected that in the short time which has been available for practising with the gelatine plates a large number of first-class pictures could have been taken by means of them; but some of the specimens exhibited in the Gallery in Pall Mall are really beautiful. In the "Sycamores on the Wharf," by Mr. Payne Jennings, of West Dulwich, for instance, not only is every leaf and its shadow in the water distinct, without spoiling the general effect, but the very atmosphere of a balmy day seems to breathe through the picture. But the quickness with which the gelatine plates act is better shown in a small landscape contributed by Mr. J. Gale, of Bermondsey, and described with the appropriate lines:

The swallow, too, is come at last.
I saw her dash with rapid wing,
And hailed her as she passed.

Over a pool in the foreground a solitary swallow was flying when the landscape was photographed, and the image of the bird and its shadow just beneath have both been secured without the slightest blurr or faintness to show that they were swiftly moving when the likeness was taken. The exhibition is also noteworthy as embracing the results of another important improvement, which, after being the subject of much thought and labour for several years, has lately been perfected by Mr. W. Willis, Junr., of Lee. This gentleman has patented a process of photographic printing in what he calls platinotype, the print being produced by means of platinum instead of gold and silver. Hitherto the photograph has been a thing of beauty, but not a joy for ever; whereas, when Mr. Willis's invention is used, it may be both. It is true that permanency was secured by the carbon process, but against carbon paper there is the great objection that while printing it is almost impossible to see the picture on it. The platinotype prints in the present exhibition are a trifle cold in tone, but they give a great variety of lights and shadows, and have the advantage of being printed on paper which does not shine. Among the other interesting things in the Gallery are some striking effects of sky and sea photographed by Colonel Stuart Wortley, four photographs of the famous Burnham Beeches by Mr. V. Heath (Piccadilly), and a number of photographs burnt on porcelain by the Autotype Company. The opening of the exhibition was celebrated on Saturday night with a soiree, at which there was a good attendance, including the President (Mr. J. Glashier), the Treasurer (Mr. J. Spiller), the Hon. Secretary (Lieut. L. Darwin, R.E.), and the Assistant-Secretary (Mr. E. Cocking). There were no formal proceedings, the evening being devoted to conversation and the inspection of the collection. The latter will remain open till the end of November, free admission being granted to the public.

[From the MORNING ADVERTISER.]

THERE was a large and distinguished assemblage of ladies and gentlemen at the *conversazione* of the Photographic Society of Great Britain on Saturday evening, when the annual exhibition was inaugurated at the Gallery of the Society of Painters in Water Colours, 5A, Pall Mall East. Like the agriculturist, the photographer has had to contend against the difficulties inseparable from an unfavourable season. Light is essential to the production of high-class work, and considering how seldom the sun has deigned to shine it is surprising that so many really favourable results have been attained as this exhibition evidences. With what extra trouble and annoyance the earnest photographer has been beset in the exercise of his seductive

calling there is here nothing to show. Results which are unmistakably satisfactory have been accomplished, but under what trying and vexatious circumstances the artist alone, were he so inclined, could divulge. However, it is not with the means and practice of sun-painting that we are concerned. The finished performances of the camera, as they are displayed in this Society's annual exhibitions, carry our minds away from the manipulative processes of scientific chemistry. Those more immediately interested in this beautiful art will doubtless view these works primarily in relation to the methods by which they have been produced, and, next, to the finished result; and such a proceeding, intelligently carried out, cannot fail to be highly interesting and instructive. In fact, much as the connoisseur and lover of the beautiful in nature and art may admire and learn from these exhibitions, it may fairly be questioned whether the photographer himself, being invited, as it were, to a banquet prepared by the most accomplished *chefs* in his or their speciality, does not derive an equal advantage from having his ideas expanded, his knowledge increased, and from being stimulated and encouraged to persevere in his vocation. This alone would be an all-sufficient *raison d'être* for these annual exhibitions. It is, however, in the spirit of an out-sider, as a looker-on at some mystic art, which, greatly as we may appreciate its beauties and feel embarrassed at its wonders, we do not profess to understand, that we offer a few comments on the specimens exhibited, from a purely artistic standpoint. In portraiture no appreciable advance seems to have been made. The triumphs of former years have come to be matters of course, such a thing as retrogression in photography being contrary alike to expectation and experience. If progress has been accomplished it is rather in processes of development than in ultimate results. No doubt the initiated will attach importance to those works produced by the gelatine plate as a substitute for the wet or collodion process. The advantage claimed for the former, being essentially manipulative, is not apparent to the mere observer, and no steps have been taken in this exhibition to demonstrate it. If the photographer had exhibited side by side a picture by each process taken under exactly similar conditions it would have been possible to compare results. It may, however, be pretty safely affirmed that the successful use of the gelatine plate, hitherto regarded rather as a possibility of the future, has become an accomplished fact, and is already having its influence on the development of the art. The two subject pictures executed by Mr. H. Garrett Cocking, son of the esteemed assistant-secretary, representing "The Fern Seller" (230), and "A Drink by the Way" (231), are by the gelatine process, and show that at least this clever manipulator has made good use of this simple material. These are both good specimens, and although Mr. Cocking has previously himself an expert in photography as applied to grouping and expression, it is clear that he has opened up a new field of research which cannot fail to add to his well-won reputation. Mr. Debonhau's two frames of portraits of children (105 and 127) are highly commendable; while, perhaps, the portraits direct from life by Mr. A. Boucher, of Brighton, are the most charming examples in the collection. They have, however, been to some extent after-touched, and, although they rank high as finished performances, cannot be regarded as the simple unaided product of the camera. The carte and cabinet portraits of children by the collodion process, shown by Mr. W. J. Byrno, are really exquisite. A series of full-length costume portraits, by Mr. H. Roher, of Chicago, have merits of their own, but are a trifle too black in tone. Messrs. E. Gregson and Sons, Blackpool, exhibit three frames of portraits which are remarkably good specimens, the tinting being almost perfect alike in its most delicate and more pronounced passages. There are several portraits by the luxograph process, taken without the aid of daylight, as well as others exhibited by Mr. H. Vander Weyde, taken by the electric light, in which the shadows are so skilfully modified that they compare favourably with pictures produced by natural light. Mr. Robert Faulkner and Messrs. Hills and Saunders contribute some fine specimens produced by the powder carbon process on opal. Amongst the novelties may be mentioned the works printed in platinotype by the inventor, Mr. W. Willis, Junr. These are printed from negatives supplied by Mr. Payne Jennings, Mr. Valentine Blanchard, Professor Stebbing, and Mr. F. Hollyer, and in each case the result is eminently satisfactory. The pictures are in tone a pure grey, charmingly soft, and altogether free from blots or blurs. By this process, which substitutes platinum for gold or silver, absolute permanence is

secured, and that oft-repeated reproach that photography is apt to fade is put out of court. Mr. R. Faulkner's autotype prints, in imitation of the old Bartolozzi mode of engraving and printing in a style resembling red chalk, are unquestionably beautiful, the three "Studies of Expression" (114) being exquisite, both in point of arrangement and execution. Amongst the landscape studies those by Mr. Payne Jennings still hold a foremost place. His pictures are produced both by the wet and gelatine processes, and are marvellous examples of pure photography. Colonel H. Stuart Wortley exhibits, as usual, several effects of sky and sea taken instantaneously. Even the foamy spray dashing over rocks in Scilly is caught with the happiest precision, as if Nature had been wooed into a focus, and then and there impounded. The utility of these graphic records of material Nature in her most evanescent moods is obvious. Unerring in point of literal truth, they bring home to the mind in all their vividness the pleasing realities which they transcribe. True, they are without the embellishment which colour affords, and it may be objected that the ozone is not there; but short of these impossibilities the forms of sea and sky, ever shifting like the kaleidoscope, are so accurately represented that the imagination experiences no difficulty in realising their fidelity and enjoying the breeze which sure enough drives those clouds and waves onwards. Messrs. Wratteu and Wainwright contribute a series of small but effective instantaneous views of the last University Boat Race. There are excellent views in Devonshire and North Wales by Mr. William Bedford; views in Skye by Messrs. Valentine and Sons; and sundry familiar picturesque "bits" in South Wales by the School of Military Engineering, Chatham. Mr. W. J. Grant contributes a considerable number of studies taken by him during the Dutch Arctic Expedition, 1878, which are not only favourable specimens of the art, but exceedingly interesting. On one of the screens Mr. Edwin Cocking exhibits a series of views in Demorara, a visit to the falls of Kaieteur, taken by Mr. F. G. Norton, a former pupil of his, and immediately below will be found a large number of Indian views by Mr. A. T. W. Fenn. Mr. T. J. Dixon's "Studies of Lion and Lioness" (111), carbon enlargement, are exceedingly lifelike. The Autotype Company and the Woodbury Company are represented by good examples of their negative and carbon enlargements. The enamel photographs—consisting of portraits, landscape, and architecture—burnt in upon porcelain and earthenware, exhibited by the Autotype Company, resemble sepia drawings, and seem to open up an entirely new field of enterprise. There are also commendable specimens by Mr. Matthew Whiting, Captain Verney, Mr. A. Donald, Mr. S. G. Payne, Mr. A. Lombardi, and Mr. Alfred S. Fisk, whose instantaneous studies of horses, dogs, sheep, pigs, &c., are worthy of all praise. As in former years, the Council have placed at the disposal of the judges a number of medals to be awarded for artistic or scientific excellence. The judges this year are Mr. H. S. Marks, R.A., Mr. W. W. Oules, A.R.A. (painters), Mr. James Glaisher, F.R.S. (the president), Mr. Valentine Blanchard and Mr. John Spiller (members of the Council), and Mr. T. M. Brownrigg and Mr. G. Shadbolt (members of the Society). The exhibition, which, as we have said, was inaugurated by a distinguished company on Saturday evening, will remain open until the 13th of November.

[From the TIMES].

THE exhibition of the works of photographers arranged at the Gallery of the Water Colour Society in Pall Mall shows in the more than 400 examples contributed by nearly 100 photographers how widely the art is practised, and to what a point of perfection it has been brought so far as manipulation is concerned. It is in this direction, however, we notice that the art which has been so completely born of science seems to conquer new ground, and not in the way of artistic feeling and those points of beauty which the painter sets himself to study and portray. Yet it has been shown by such work of the lens, guided by artistic feeling and taste, as those remarkable portraits produced by the late Mrs. Cameron, that the capabilities of photography are much higher in the hands of an artist than in those of an operator. Certainly the prime value of the photograph in an art point of view is its true representation of light and shade, and the nice gradations which give perfect form with the charm of tone and effect. Applied to portraiture with all this resource, as it rarely

is, we should expect to see a much more satisfactory development than is to be observed generally in the vast host of likenesses which crowd the shop windows. Judging from the great nicety of gradation and tone shown in many of the portraits and other specimens exhibited here, we should say that much of the beauty which the genius of Rembrandt gave to his portraits lies within the reach of an artistic photographer. The subtleties of life and expression are reserved for the painter's and the sketcher's hand alone, perhaps, but who shall say that these are impossible to the photographer who has added the something beyond his perfect lens and his instantaneous sensitive surface? If the tones and expression of a voice can be transmuted into matter and reproduced precisely, photography has yet to find its Edison. The perfecting of the instantaneous method, which has recently made an important advance in the use of a film of sensitized gelatine instead of collodion, will no doubt lead to the production of better portraits. The employment of platinum instead of gold and silver, as invented by Mr. Willis, has evidently great advantages in obtaining pure gradations, and the tone being gray, like that of a lead pencil drawing with a dead surface which artists call "matt," gives a picture more agreeable to the eye, with an airiness of effect much more natural than the ordinary tint we are accustomed to in photographs. There are several excellent specimens of this process in the Exhibition contributed by Mr. Willis (Nos. 341 to 352), and others (333, 339), by Messrs. Cobb. We noticed also some well-chosen landscape subjects, by Dr. Huggins, which have been developed a month after having been taken on the dry plate. As we are informed, there seems to be no limit to the duration of the impression once received, and the print is said to remain permanent, or, at any rate, far more so than by the gold and silver process. As good examples of instantaneous photography, there are several very beautiful skies and skies by Colonel Stuart Wortley, who maintains his position at the head of all in this difficult branch of the art, which he was, we believe, the first to discover. Mr. A. Clout's views of a regatta at Sandown, showing the yachts at an exciting turn in the race, and numerous figures on the beach, are also remarkably successful in catching the rapidly-changing scene. In landscape there is nothing in the Exhibition which carries photography higher than it has been for some years past in the hands of such experts as Mr. Vernon Heath, Mr. Bedford, Mr. Frith, and several others whose works are well known. It may be said, however, that in this direction the difficulties appear to be almost insurmountable, though here, as in portraiture, much is obviously to be attained by the study of pictorial beauty in preference to objective detail and exact reproduction. Some of the most interesting of the photographs as showing artistic feeling are the albums containing various rustic interiors, rustic figures, sheep-shearing; groups of objects, especially one of mushrooms, taken by Mr. Frederick Hollyer by the platinotype process. The great value of photography has, of course, long been recognized and systematically adopted for military and all expeditionary purposes of exploration, and of this there are many good examples in those contributed by Lieutenant Darwin, R.E., and the School of Military Engineering, though none precisely of a military nature, which is to be regretted, as these would have a special interest. Good photographs of Pearson's defences at Ekowe, and of the ordinary lager of the troops on the march in Zululand, or, better still, the biscuit-tin and mealie-bag barricades of Rorke's Drift, would be regarded with the deepest interest. These no doubt have been taken and are preserved in the School at Chatham. We have, however, some highly interesting views of the positions of the Dutch Arctic Expedition of last year, taken by Mr. W. J. Grant, of Liverpool, by the collodio-bromide dry plate process. Those also of incidents of the war in Armenia, taken by Nikilin, of Tiflis, are remarkable for characteristic selection and a nice pictorial tone with very perfect representation of the figures and places. As to the portraits, it would be difficult to pronounce which are the best where so many seem to meet the practical requisite of a good likeness, and when, as in some cases, the work of an artist has been employed in touching out the defects of accident or the deficiencies of the photographic process. Those taken on dry plates (295) seem to be excellent, and those taken by the electric light are if anything more delicate in the gradations than the ordinary daylight portraits, and it may be a question whether this may not prove to be the preferable mode. The exhibition will remain open for some weeks, and in November the medals will be presented to the successful competitors in the present exhibition.

THE PHOTOGRAPHIC EXHIBITION.

THE annual Exhibition of photographs held by the Photographic Society of Great Britain was opened on Saturday evening last, the 4th inst., in the Gallery of the Water Colour Society, Pall Mall East. The opening was inaugurated by a *conversazione* of the members and their friends, who gathered in large numbers to see the new pictures. A more numerous and happy-looking assembly we have rarely seen within those walls.

The Exhibition is a very good one, in many respects more interesting than usual. In many respects it is different in character to most previous Exhibitions. There are fewer large frames of portraits, fewer large landscapes, and fewer enlargements; but there is a more varied collection of photographic pictures in which the art element is prominent. It is probable that the programme of prizes offered has had something to do with producing this characteristic. When prizes are offered for good things without defining by a hard and-fast line the precise style, good things of any style and size suited to the metier, the taste, or the opportunities of the artist will be produced. Whereas if the medals were offered for sets of portraits or landscapes of a specific size, the Exhibition would probably teem with frames of portraits and landscapes. It is true we miss many old and always admired contributors. We find nothing from Valentine Blanchard or Robert Slingsby in portrait studies, nor from Mayall, Chaffin, Warwick Brooks, J. M. Young, Ford Smith, Nesbitt, nor A. Wilson, whose portraits and figure studies have adorned many former exhibitions. In landscape, we miss the familiar gems of Henry Cooper, Wm. England, Bool Brothers, H. Baden Pritchard, Reuben Mitchell, Wm. Brooks, R. Viles, B. Wyles, and many others. But *en revanche*, we have the return of some old exhibitors, whose works had been missing from recent exhibitions. We are glad to hail the return of H. P. Robinsou, with his grand example of chiaroscuro; of Adam Diston, of Fyfe, with some charming work; of George Bruce, of Dunse, with rare pictorial work; of Joseph Gale, with some of the gems of the Exhibition; of Mr. and Mrs. Glen Payne, whose works could be ill spared. These, and some new contributors, pretty well supply the regretted vacancies.

We do not, on a first glance round the walls, enter into any detailed criticism or systematic mention of the contributions, but briefly mention a few of the things which first arrest attention; and in doing this we give *place aux étrangers*. The Exhibition is enriched this year by an extensive series of contributions by Mr. H. Rocher, of Chicago. We have had occasion before to speak of the high quality of Mr. Rocher's portraiture, when reviewing some examples he was good enough to send us some time ago. Good as his work then was, he has progressed since considerably, and it is not too much to say that his work in its entirety will compare favourably with the majority of the best on this side the Atlantic. His specimens range from the "pauel" or "promenade" style to large pictures

of sixteen by twelve inches. Lewitzky sends from St. Petersburg a charming cabinet portrait of himself, and M. Scamoni, from the same city, a fine specimen of "heliogravure." Signor Bossetti sends from Italy some interesting Italian views; and these constitute the whole of the foreign contributions.

Notable amongst home contributions, a feature of striking interest is found in the large display of ceramic photographs sent by the Autotype Company. These are unlike anything hitherto exhibited in photo-ceramics: they are of a sepia tint, and produced, apparently, on porcelain plaques. Unlike those produced by what is known as the conversion process, in which a silver image is converted into platinum, iridium, or other noble metal, and then fired in the muffle; and unlike those in which a vitreous powder is dusted on an adhesive image, these are produced by means of a tissue containing a vitreous substance in place of the ordinary pigment used in carbon printing. The tissue process of producing enamels was first suggested in our volumes soon after Mr. Swan described his process of carbon printing. A Mr. Firling, of Dorchester, was the first, so far as we know, to work out the process, not, however, very successfully, and he kept the details of his method secret. The Autotype Company now for the first time appear to have worked the matter out with real success, and on a commercial scale. Mr. Robinson sends only one picture this year. Unambitious and unpretentious, it is, however, a great triumph in securing painting-like effects by means of photography. It is entitled "Between the Lights," and represents a cottage interior where, as even-tide comes on, and a little girl sits reading, firelight contests with the weakened light of day, and the little student is uncertain upon which to rely. It is a marvellously fine piece of chiaroscuro. Mr. W. J. A. Grant's frames of Arctic pictures are a surprise to everybody. They were produced whilst with the Dutch Arctic Expedition he recently described in our pages. Pre-eminently interesting, by reason of their subject, as these pictures must always be, we have not been prepared by former experiments for triumphs of photographic or artistic skill. Mr. Grant has, however, not only produced some interesting records of Arctic effects, he has given us really good and artistic pictures. Amongst the most striking objects in the Exhibition are Mr. T. J. Dixon's studies of Lion and Lioness, which are marvellously grand, and compel regret that they were not in existence when Sir Edwin Landseer was modelling his Trafalgar lions. A pair of portraits at the upper end of the room, one of a lady, the other of a boy, exhibited by Messrs. Hills and Saunders, will arrest attention, and compel admiration. They are carbon prints on opal, enlargements from gelatine negatives, and of charming excellence. The boy is especially fine: the admirable pose of the full-length figure, the simplicity and perfection of the composition and background arrangement, are beyond praise. The most striking frame of portraits is a very fine collection of large portraits by M. Boucher, of Brighton, rich, vigorous, and delicate, admirably modelled, and unusually free, for such portraits, from retouch.

The value of artificial light for photography is well illustrated by fine specimens produced by the Luxograph, and by other excellent work by the electric light, as used by Mr. Vander Weyde. Genre photography is well represented by Adam Diston, whose picture from a combined negative, entitled, "Henry Kirk White in his Study," is a rare gem. Mr. G. Bruce has some excellent genre studies, printed in collodio-chloride of silver. His "Farrier's Shop" is perfect. Mr. Gillard sends some very excellent studies in a similar line.

As might have been anticipated, gelatine emulsion is well represented, especially in rapid work. Col. Stuart Wortley's studies of sea and sky, chiefly by the gelatine process, are amongst the finest in this kind which have ever been produced. Two little studies of "Brixham Trawlers," by Mr. Joseph Gale, are simply delicious. A series of scenes representing English country life in the

field, such as "Thrashing and Thatching," "Carrying and Gleaning," the "First of September," and many more by Mr. S. Glen Payne, are marvellous for instantaneity, as proved by the presence of scores of moving figures; but they are more than this—they are fine pictures: they are fine landscapes, full of happily grouped figures. Mrs. S. Glen Payne's groups of flowers are as delightful as ever, and her group of game, "Fish and Moor Hens," is almost too tempting.

We must conclude our first glance, however, and shall commence a systematic notice in our next.

THE PRIZES.

Medals have been awarded by the jury to the following exhibitors:—Mr. S. Glen Payne, Mrs. S. Glen, Mr. Roher, Mr. J. Gale, Mr. Adam Diston, Messrs. Hill and Saunders, Mr. Dixon, Colonel S. Wortley, Mr. W. Bedford, Messrs. Russell and Co., Mr. Faulkner, and Mr. Cobb. In our next we shall give details of the pictures securing the awards, and also a list of honourable mentions.

STRETCHING OF GELATINE NEGATIVES.

THE enormous boon in convenience and rapidity conferred on the portraitist by the gelatine emulsion plates is doomed, it appears, not to be given without qualification or drawback. Like the tricky spirits of Elfin land, of whom Puck is a type, the negatives at times assume strange transformations. A correspondent describes, on another page, one of these strange vagaries, in which, having taken a pair of carte negatives of a child, he is astounded to find, when he returns to the dark room, a pair of cabinet negatives. The film had spontaneously stretched or expanded to nearly double its original superficies. Strangely enough, and very fortunately, it had thus expanded in even proportion, and as the carte negatives were intended for enlargement, no harm was done by the expansion, the film not even suffering the fate of the frog in the fable.

But this illustration shows a possibility which is somewhat startling. Cases might occur when the change of size might be very inconvenient, and, worse still, and not improbable, cases might occur in which the expansion was irregular, instead of even and in due proportion. In the present Exhibition there is an illustration on the table, exhibited, we believe, by Mr. Fry, of an expanded and distorted gelatine negative, the sitter being made to pull a long face very literally. We do not know the precise history of this negative, but we recently inspected a somewhat similar, or even more grotesque, monstrosity. It was the portrait of a lady whose face was distorted to something like twice its natural length. The gelatine negative, when first produced, was perfect, but the photographer, somewhat in haste to complete his work, had thought it safe, when the negative was surface dry, to hasten perfect desiccation by holding it before the fire. As soon as the gelatine—still containing a little water—felt the heat, it began to expand and stretch itself on the plate, producing no direct rupture or apparent injury, but gently and evenly stretching in the direction in which it was held, slipping, in fact, down the plate, with a result which can easily be imagined. The photographer in whose hands it occurred showed it to us as a simple plan of producing photographic grotesques, as it was manifest the direction of expansion was, at least to some extent, under control.

We can readily conceive that some of our conservative readers may regard these facts as signing the death warrant of gelatine for portraiture. The conclusion is, however, by no means necessary. The possibility of accident by no means demonstrates its necessity. It simply points to the need of extra care in avoiding it, and its causes. There exists, we have been told, at the present time, in the cellars of the National Gallery, an interesting picture by a great modern painter, who was distinguished by his passion for experiment with varied mediums to supersede "honest liuseed oil." In using one of these mediums, containing wax, he painted the face with a larger proportion than

usual, and the picture subsequently, hanging in its place on the walls of the Gallery, chanced to receive unusual warmth from the sun. The waxy medium softened, and the eye of one of the figures slipped from its place, sliding to the bottom of the cheek. It is said that the picture now stands upside down, in hope that the eye may slip back again! We do not vouch for the truth of the story; but we have heard it narrated. No one would, we apprehend, deduce from the story a moral antagonistic to oil painting. The moral would be simply to the effect that care must be used as to the medium to be employed. So with gelatine negatives: the moral of the vagaries described is the need of care in keeping damp gelatine films far from the fire, and the desirability of avoiding leaving such films soaking in water longer than necessary; also the importance of an early use of the alum bath.

FRENCH CORRESPONDENCE.

PHOTOGRAPHIC PRINTING BY MEANS OF A REAGENT ACTING ON SPECIALLY PREPARED PAPER—PHOSPHORESCENT PHOTOGRAPHS—FLUID FOR ENGRAVING ON GLASS—PHOTOPHONOGRAPH—NEW WORK ON PHOTOGRAPHY FOR ARTISTS AND TOURISTS.

Another Method of Obtaining Photographic Prints by Means of the Papyrograph.—If my readers will be good enough to refer to my last letter, in the PHOTOGRAPHIC NEWS of the 26th September, they will see that I spoke of a method of applying the papyrograph for obtaining a photographic print. This I proposed to effect without the use of the roller, but merely by means of pressure from a permanent supply of ink capable of penetrating through the pores of a paper of which all the parts not affecting the drawing to be printed remained coated with an impervious reserve. Here we are able to recognize the idea of an easy and rapid printing process. But there may be another method of applying the papyrograph in photography, and such an one has been suggested to me on reading the letter which that distinguished *savant*, Dr. Vogel, has published in the *Bulletin Belge*. He refers to a new—but, as yet, secret—process invented by Herr Kolk, an engineer in Berlin, for taking prints, not by means of a fatty ink, but by some reducing substance acting on a paper which, according to Dr. Vogel, is evidently impregnated with ferrocyanide of potassium and chloride of iron. The reducing substance produces on the paper an image in Prussian blue. In fact, it is a process for obtaining a picture by chemical action combined with mechanical impression, and the subject generally is full of interest; for suppose the spongy pad of the papyrograph to receive a charge of a solution of some reducing agent in water—pyrogallie acid, for instance—and that the paper has been impregnated with the substances above mentioned, the reducing substance will act through the porous parts at each impression, and produce an image on the paper prepared with ferrocyanide. The action will be similar to that which takes place in the printing and dyeing of woven fabrics without the intervention of photography. I do not suppose that this is the actual way in which Herr Kolk pulls his prints, but I mention it because I see that it is a method by which the required result might be obtained.

Phosphorescent Photographs.—At the Exhibition of "Scientific Objects Applied to Industry," which still remains open at the *Palais de l'Industrie*, in Paris, I lately observed some photographs which are called phosphorescent. It is an error to call them so, because, in fact, it is the background on which they rest that is phosphorescent, the image standing out in black from this phosphorescent background. But there would be an easy means of producing the reverse effect, and that is of obtaining a luminous map on a dark background. To do this it would be only necessary to take powdered sulphide of strontium, and to use it in the same way as are the metallic oxides in the production of enamels. A photograph could be taken on a deliquescent film, then the image would be hygroscopic

to an extent proportional to the intensity of the light which acted on it, and having developed this latent image by sprinkling on it finely-powdered strontium sulphide, it could be transferred to a dark-coloured paper. This paper, after being exposed for some time to a strong light, and then hung up in the dark, would show a luminous image with a beautiful phosphorescence of a light blue colour. To get the proper powder for this process, a thin layer of a mixture of 33 grammes of strontium carbonate with 100 grammes of fine sulphur must be calcined in a large crucible. If it be possible to produce these effects of phosphorescence by means of photography (and I mean to experiment in this direction), the spiritualists would be able to devise many ingenious tricks. Let us suppose a sitter having his portrait taken by the electric light, and that the latter is, after a time, suddenly extinguished; the model, being in the dark, will produce no effect on the plate; but if a phosphorescent image is made to appear in the required spot, a copy of it could be impressed on the negative. I make a present of this idea to those whom it may concern; probably it is not of much value, but a joke may be occasionally allowed as a sort of protest against the monotony of photography pushed to extremes.*

Fluid for Etching on Glass.—At the same Exhibition, where there is quite a crowd of ingenious inventions, I observed a new kind of ink (the invention of M. L. Kessler) for etching on glass, which, I think, will be found useful to photographers in many respects. In what way it can render such service it is not necessary to particularize, as the instances where it can do so are very numerous. By means of this fluid—which is not dangerous to handle, like hydrofluoric acid—and with an ordinary pen, writings and drawings may be executed on glass, and scales can be graduated; every spot that the fluid touches is found to be etched to a considerable depth. After having written or traced a drawing on the glass, all that is necessary is to wipe the surface with a sponge dipped in water. I am not able to say what is the composition of the fluid, but I am told that it consisted of ammonium fluoride. The results obtained by the use of the fluid are certainly very remarkable, and for the benefit of those of my readers who wish to try it or to examine it, I give the address of the shop where it may be purchased in Paris—M. A. Loiseau Fils, 29, Rue Richelieu. No doubt an agent for the sale of the fluid lives also in London, but I do not know where he is to be found. The price of a small gutta-percha bottle of the fluid is one franc. I purpose going in detail through the whole of the Exhibition at the *Palais de l'Industrie*, which has been made much more complete and interesting than I ever thought it would be, and if I find any novelty worthy of the notice of my esteemed readers, I shall have real pleasure in making it known. My task in this respect will be rendered easier from the fact that I have been nominated to the scientific commission specially appointed to draw up a report on all the objects which, from a purely scientific point of view, are deserving of mention.

Photo-Photography.—Thus, a large number of photographs of all kinds are shown in the Exhibition. Now, as both by taste and profession, I am accustomed to refer everything to a photographic standard, the idea struck me whether it would not be possible to apply photography to the phonograph. The question is whether we could, after having traced on a sheet of tinfoil the series of vibrations which constitute either a sentence or a tune, reduce to a plane surface the whole of the prints, which are more or less deeply stamped in the tinfoil, and which correspond to the more or less numerous and vigorous vibrations. This sheet of foil can be made, as is well known, afterwards to reproduce the words that are impressed on it, only by keeping it free from any kind of pressure. Besides, these fillets, such as they are, could only be used

again by employing a phonograph moving in a straight line instead of one supplied with cylindrical fillets, on which the vibrations are impressed in a special curve. But to one of these fillets, impressed in a straight line, a mould could be applied by a method similar to that of the Woodbury process, from which a print could be obtained with the points no longer more or less stamped in, but with those points more or less sunk, according as they correspond to the depressions more or less deep. Thus we should translate the differential effect from a curved to a plane surface. By means of photography we could then reproduce these fillets, which must be of a certain initial length in order to reduce them, preserving at the same time the different intensities of tint corresponding to the various depths of the impressions. From this point to that of finding a method of reading is no doubt a very long step, but one which I have a vague idea is not insurmountable—perhaps, in a condition of the first degree of possibility. Meanwhile I intend to carry the investigation further, proceeding from the simple to the complex. I shall commence by observing what is the appearance of a single word, or two simple words—for instance, *Bonjour, Monsieur!*—pronounced by a dozen different persons with varying intonation. I shall then try to discover the law embodying these different traces. After that, I would again take a dozen impressions of another series of sounds—such as *Pas mal, et vous?*—and it may be possible, with some patience and a little ingenuity, to arrive at a disentanglement of this skein of vibrations.

New Photographic Literature.—Our collection of literature bearing on the art of photography is continually being enriched by the addition of new technical works. This really valuable movement we owe to the intelligent initiative of the special publisher of all our photographic works—M. Gauthier-Villars, to whom our science is much indebted for the zeal and disinterestedness which he manifests in bringing into notice everything that he thinks will have a favourable influence on the progress of photography. On the present occasion I refer to an interesting work by M. Pelegrin, giving a description of a new process on oiled paper, simplifying the apparatus, and making easier all the manipulations, with instructions for constructing all the necessary instruments. M. Pelegrin is, perhaps, a little late in the field; we have now-a-days the rapid processes with dry plates and emulsions, which have completely overthrown the old methods of using dry iodized paper, so slow in printing and developing, and, besides, so full of grain, however fine it might be. Nevertheless, the fine days of these amateur processes—no less than those of collodion, wet or dry—are not absolutely over. Moreover this work—if we can set aside the oiled-paper process, and replace it by the more complete and more rapid ones with dry emulsions that are now so well known—contains some very excellent advice of every kind, which will be of great service, whatever may be the process employed. The amateur of photography cannot fail to derive advantage from the perusal of this little book, which is written more especially with reference to art in photography, and for the benefit of the painter, who cannot do better than add the photographic camera to his other travelling impedimenta. LEON VIDAL.

ARTISTIC COMPETITION.

BY E. DUNMORE.*

I HAVE a proposal to make this evening in connection with this, the South London Photographic Society, which, I think, will be calculated to advance artistic photography by inspiring the members with a spirit of emulation in one particular direction. It is patent to all that the *art* qualities of our photographs is the weak point, the vulnerable heel, the tendon Achilles (if I may so call it) of the photographic frame, for the manipulative qualities are

* Our esteemed correspondent has overlooked the circumstance that we some months ago described this process as an actual fact, and mentioned results we had seen by Mr. Woodbury.—Ed.]

* Read before the South London Photographic Society.

almost, if not quite, 'unimprovable'; and it is with the idea of eventually making the art-qualities more on an equality with the manipulations that I make the following suggestions.

That our President shall, at each monthly meeting announce a name, title, or designation, and during the month ensuing members of this Society shall produce photographs of single figures or groups to illustrate this title or name. The pictures competing to be judged *only* for their *artistic* qualities; no restriction to be made as to size of photograph, in order that any photographer may, with the means he has at command, be able to join in the competition. Such pictures to become the property of this Society, and once yearly, at one of our meetings that may be decided upon, a jury formed of artists—not professional photographers—shall decide upon the merits of the photographs thus exhibited, and a prize or prizes shall be awarded for the most skilful picture or series of pictures that have been exhibited during the year.

As to the shape the award shall take, that is a matter for our consideration. For my own part I would propose that a medal be designed and struck especially for this purpose in silver and bronze, so that such a medal, being intrinsically valuable, as well as a reward for merit, would be deemed worth the trouble of acquisition, and stimulate competitors to do their best. I think it would also induce many to join our Society. This is, however, a collateral advantage.

The mode of working out the plan should be similar to other competitions of a like nature. A mark or motto should be attached to each picture sent for the purpose of reference, and a sealed envelope, containing the name and address of the producer, with a duplicate of mark or motto, to be sent at the same time as a means of identification, but not to be opened until the end of the time stated, and after the award of the prizes. The photographs to be sent in to the secretary a few days—say not less than two—before each meeting.

The question of who is to pay for the medal or prizes is no doubt an important matter; but, bearing in mind the amount of a recent subscription from a few photographers for another purpose, I do not think there will be any difficulty in that respect. If even instead of giving presentation prints the money was devoted to this purpose, I am not sure if it would not be a good thing. We have now the whole of the session before us in which funds might be accumulating. However, supposing the necessary funds are not forthcoming (which is perhaps an idle supposition), a friendly rivalry of this nature would be exceedingly interesting.

I suggested figures or groups, not precluding landscape, if such should be sent in; but as the opportunities of the landscape man are so few, in comparison, during the winter months, it will practically limit the class of subjects to figure.

I would suggest that gentlemen falling in with my views on this subject should send pictures for our very next meeting, and, by complying with the rules here sketched out, be in a position at the end of the session to take their chance for a medal, if it be eventually decided to offer them.

I will now conclude by re-stating the conditions I think suitable for the purpose:—

1. Pictures may be of any size, unmounted, or mounted on plain mounts, and either landscape or figure subjects.
2. A private mark must be attached to each, but no name or address.
3. An envelope, sealed and containing the private mark and real name and address of sender, to be forwarded with the pictures.
4. That such envelope shall remain closed until the end of the session, after the award of prizes.
5. That all pictures intended for our monthly meetings shall be forwarded at least two clear days before such

meeting to the Secretary of this Society, who shall exhibit them to members only on the nights of our meetings.

6. That two artists, not being photographers by profession, shall be chosen to adjudicate upon the merits of the pictures, and from whose decision there shall be no appeal.

7. That one or more medals or other prizes shall be given for the most successful picture or series of pictures.

8. That all exhibits become the property of the Society, and be placed in an album or portfolio for the purpose of exhibition.

9. That at each meeting the President shall announce the name or title for the subject of the pictures to be exhibited at the meeting next following.

These are, I believe, the principal necessary conditions, and all else that is required is your earnest co-operation.

FAILURES IN CARBON PRINTING.

BY W. H. DAVIES.*

A PAPER like this, written confessedly to get rather than give information, must of necessity be of extremely slight interest; yet what can one do when he receives an almost imperative command to get something ready for next meeting, and when that request is couched in the gently persuasive touching tone of our worthy secretary? Now it seems to me that he has come to the wrong man this time, for like Canning's knife-grinder, I have no story to tell; but if the mere request should stir up some of the quieter—or, shall I say, lazier members. By-the-bye, I dare not say, for I have been amongst (at all events) the latter category. Laziness is decidedly catching; it is a good deal like scarlet fever. I've known it to catch a great many, especially ladies. Now, I didn't mean that laziness did that; no, it was the scarlet. But why should it be that we, who number among our members several of the—the what shall I call them, is it interesting creatures, or what?—should not have a paper from a lady member? for I feel well assured that it would meet with a most grateful and hearty reception. But, Mr. President, that is no reason why many of the quite as bashful and more than backward of our ordinary attending members should not make an effort—I said an effort, I should have said an annual supply of efforts—and give us the results of their work, of their experiments, of their experiences, of their difficulties and bothers, of their successes, or, like your humble servant, of their failures. I most decidedly think they should, and would most earnestly impress upon them this fact, that no body such as this is can go on and continue healthy and do good work unless it has the continued assistance and work of the members, and especially of those who have not taken heretofore the proper kind of interest in the work of the Society. If we are to go on succeeding we must also progress, and to that end all should assist, more especially the younger members; and the truest assistance is to keep the secretary well supplied with papers, so that it shall be a question of the Council which is to be taken first.

But I can hear the question, what on earth has this to do with the subject of failures in carbon printing? Well, I can only say, in reply, that if the questioner had the same reluctance to tackle the subject as I have, he would have remained as I should have liked to have done—absent from the meeting; but as this is impossible, and as something must be said about the subject, one may as well take it up at once, and ask, What is the cause of blisters? with the corresponding query, What is the cure?

—Blisters are naturally divisible into varicous kinds; in fact, they divide the film from the support, and the first idea is at once to say, "Oh, it is only a bubble!"—that's a mistake in expression, I should have said air-bell—caused by the film not being closely attached to the support. Be it permanent, or otherwise, this is very probably one of the

* Read at a meeting of the Edinburgh Photographic Society.

causes, but it is only one. The air enclosed under the film naturally tends to expand when the hot water is applied, and so, growing larger by the heat, lifts the film from the support, thus causing a blister. The cure in this case lies in ensuring the closest possible adhesion of the surface; and the best way, in addition to the squeegee, is the placing of each print above the other, and subjecting to considerable pressure before development, and that pressure to be continued for but a short time.

Another failure is the transfer paper not being perfectly and properly coated. Many of my prints have been spoiled through this. Remedy: more care and caution on the part of those who prepare the paper. Still another cause of failure consists in not soaking the transfer papers sufficiently before putting them together preparatory to development, and to this must be added undue haste in the development by using the water too hot, or by developing too soon after contact; this last is fruitful of failures. A frightful source of failure is the quality of the negative; and if a silver printer were to make use of his silver printing experience, he would come to grief, as, for instance, a better print is got from a dense negative with a weak bath, and with a weak or thin negative a strongly salted paper is best. With carbon this is reversed; the denser the negative, the stronger must be the bichromate bath, because the weaker the bichromate, the less it takes up the high lights, and the more black-and-white is the result, and so leads to a large crop of failures. Temperature has much to do with the failures in pigment or carbon printing. Do not let the bichromate bath fall below 56° Fahrenheit, nor rise above 80° Fahrenheit, as then the gelatine film does not act as one would expect a reasonable film to behave, but displays sundry vagaries in the swelling line, that no decent or respectable gelatine or gelatinous film ought to do. Mem.—If you want to avoid some kind of failures, keep up the temperature of the bath, especially in winter. A fruitful source of failure is in the use of newly-made tissue, and this points to the need of keeping up the supply. Much better results are got (speaking from my experience) from stock-paper which has been in the house for six weeks or a couple of months, than from any freshly-used from the manufacturer's. How this is, or should be, I do not know; but that it exists is certain. The older tissues are more capable of giving the more delicate half-tone, and they stand washing and development much better. The newer-made material seems to be more able to produce that class of failure known in long past days of bad photography as soot and whitewash.

An acid bichromate bath is one of the causes of insolubility. I suppose from the rough and ready mode of crystallization, there remains a proportion of the chromic acid, and this undoubtedly produces a crop of failures; but they can be easily avoided by neutralizing or even rendering the bichrome alkaline, in which state, I think, it works not only better, but is also more sensitive, and remains without that tendency to insolubility which that with the acid reaction so often has. There may be other causes, and I should like to know them.

Light.—One of the curious experiences is caused by the caprice of the photometer, no matter which or by whom constructed. Even if I myself fail to indicate, there are certain states of the weather—with varying amount of actinism present. Say we take a photometer with the register of silvered paper, that register on a dull day will not give the same result as it will on a day of bright sunshine, or even a moderately bright day, and thus leads to many failures.

I think that either I or some other clever fellow (*sic*) must proceed to invent a coloured bichrome test, to use for pigment prints, which will register more accurately the varying qualities of light.

The greatest of the failures I have been able to bring before you this evening in the paper I have just read, and which is not worth reading, but only to be used as padding to fill in the part of an evening.

Correspondence.

INSTANTANEOUS SHUTTER.

STR,—As you have thought my shutter worthy of notice, I must add that I have made a great improvement in it. On the slide I have affixed two strips of card, leaving space to run another strip of card on the top. This strip is perforated with a variety of openings, as follows:—

a coincides with the aperture *d* (fig. 3, page 477), *b* diminishes the length of exposure, *c* answers the purpose of a small stop, *d*, *e* and *f* give still shorter exposures; *g* will answer for the purpose better than the diagram on page 477 for diminishing sky and increasing foreground exposure, *h* still more so; *i* gives a lengthened one. The whole is blackened with photographic black on both sides.

Now, before drawing the shutter, I decide on the opening best suited, and then pass the card (fig. 5) till the selected aperture is over *d* (fig. 3), and draw the slide back to cover the lens. The shutter is then opened, a sharp stroke of the hand shoots the slide across, and the exposure is complete.

I enclose a print from a negative I thus took with the opening a last week, on one of Wratten and Wainwright's plates, and I think you will say it was successful.—I am, yours, obediently,
SMUDGE.

STRANGE FREAK OF A GELATINE FILM.

STR.—A few days since, while working some of W. and W.'s gelatine dry plates, a somewhat awkward and very remarkable accident occurred to one negative in particular.

A lady and gentleman brought a baby to my studio to be photographed, wishing a cabinet size group. The baby taxed not only my patience and skill, but also that of its parents, so that the possibility of having a cabinet photograph was out of the question. Seeing this state of things, and for obvious reasons, I resolved to do it carte size, and, if necessary, enlarge it afterwards. But, thanks to the flexibility of gelatine, I was saved this trouble. The plate having been exposed, was developed with the usual bromide and ammonia developer; after a thorough washing was placed in the hypo bath; when taken out was examined, found perfectly sharp, baby still, and happy *pa ditto*. Now comes the most remarkable part of the affair.

After I found the negative satisfactory, I placed it in the tray, turned the tap on, and left it while I went to communicate the good tidings to those in the studio. Knowing the toughness of the gelatine films, and the copious washing these plates require, I left the water still running while I went to show my sitters out. On my returning to complete the operation, imagine my surprise to find, instead of the negative, nothing in the tray but a perfectly clear glass. My first thought was, had the film become transparent by some unforeseen phenomenon; as I thought it utterly impossible that the film could have washed off, as there was no sign of "frilling," and in so short a time. However, it did so, and I had the satisfaction of finding the babe and its *pa* hanging on to the side of the tray. Another moment and they would have been lost. With care I succeeded in getting the film back into the dish; found out the right side; then, with my fingers, drew it on the glass from whence it came. (I was using the double carte cabinet size plate.) But what have I here? The film overlaps the glass by about half-an-inch every way; and, instead of two cartes, I have two cabinet size pictures. More arrivals compel me to lay aside the tray of mysteries. After a lapse of nearly an hour, I am able to resume operations. My first performance was to cut the film in half, separating the two pictures. (Had I have thought of it at the time my plan would have been to have floated it upon

a large plate.) However, I was successful in getting the two halves safely landed on two cabinet plates; and when sufficiently adhered to the glass, was able to examine them, and, I must say, if ever I sighed a sigh of relief, it was then. There was my carte negative beautifully, proportionately swollen to a cabinet picture, or nearly double the original size, without the least sign of distortion. The cabinet proofs were sent home, and gave such satisfaction that not only did they order well, but gave an order for an enlargement.

This will tend to prove what an amount of rough usage these gelatine films will stand; and further, that in any case of emergency, when common sense and tact are required, if only met with care and love for the work in hand, many seemingly hopeless cases might be mastered, and turned to a profitable account. I can only say, always be on the safe side; use always the alum bath to every plate. Had I have done so, this would never have happened.

C. E. WYRALL.

VARNISHING TRANSPARENCIES.

DEAR SIR,—Can you, or any of your correspondents, kindly inform me if lantern transparencies can be coated with albumen instead of using varnish, and, if so, the best means of preparing and applying?—Yours very respectfully,

W. J. CHAPLIN.

[Albumen can be used, of course, but with what advantage we cannot say. Possibly some of our readers, who may have had experience, can supply a hint.—ED.]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE first meeting of the session of this Society was held in the Gallery at the Society of Arts, on the evening of Thursday, October 2nd, the Rev. F. F. STATHAM in the chair.

The minutes of some previous meetings having been read and confirmed,

THE PRESIDENT referred to the weekly meetings held in a spontaneous and informal manner at the studio of Mr. Brittlebank during the summer, and regarded the meetings as a happy illustration of the enthusiasm and desire for improvement which existed amongst many of the members.

MR. COBB then read a paper on the "Photographic Signs of the Times" (which will appear in our next.) After a brief conversational discussion,

MR. BRITTLEBANK read a report of the proceedings of meetings held at his studio during the summer, as follows:—

MR. PRESIDENT and GENTLEMEN,—Since we had the pleasure of meeting here in June last, most of you are doubtless aware that a large number of members of this Society have held weekly meetings at my studio in Tottenham Court Road, and in accordance with the desire of our President and Secretary, I have kept a short record of the transactions which have taken place from that time to the present. I do not propose to make any lengthy statement of the interesting discussions which have taken place, or the many ingenious contrivances which have been shown, as it is scarcely possible for me to do full justice to them. I shall therefore simply confine myself to an enumeration of the heads of the subjects, and name the principal objects of photographic interest which have been brought forward by various members.

The first meeting took place on Wednesday, June 18th, when about twenty members were present.

MR. AYERS exhibited an apparatus by means of which any desired portion of a negative can be obscured, leaving only the part required to be copied or enlarged visible; also an improved focussing magnifier. The remainder of the evening was occupied in discussion on gelatine work, and many interesting specimens were shown by Mr. COWAN and other members.

JUNE 25th. MR. SAMUEL FRY gave a demonstration of the development of the Kingston Bennett plates, showing the method of intensification.

JULY 2nd. MR. COWAN exhibited a movable background by means of which as many as twenty different views can be mounted in the same space as usually occupied by one. Other fittings were then shown by various members, including a new

blind roller and ratchet, an ingenious cleat, and an instantaneous shutter by Mr. HARRISON.

JULY 9th. MR. COWAN described a method of intensifying gelatine negatives, exhibiting a double negative, one figure of which had been treated with chloride of copper, afterwards washed, and followed by second application of alkaline developer.

JULY 16th. MR. WARNEKE in the chair. He exhibited a large number of Russian views and typical portraits of the inhabitants. MR. HAZARD showed the effects of damp on gelatine negatives. A long discussion followed, the Chairman conclusively proving that the crystalline appearance was due to physical, and not chemical changes.

JULY 23rd. The chair being occupied by Mr. HENDERSON, MR. WEAVER exhibited an instantaneous drop shutter, also one for studio use. MR. HENDERSON then read a paper on a new developer for gelatine plates.

JULY 30th. MR. PAYNE JENNINGS in the chair. Some nickel plated steel springs for printing frames were shown. MR. HENDERSON then described a modification of the developer introduced by him, consisting of substitution of silicate for ammonia.

AUGUST 6th. Chairman, MR. COWAN.—MR. J. T. LANE exhibited a new exposing shutter for the camera. MR. HENDERSON showed a new dipper for preventing plates slipping off while in the bath. MR. AYERS showed a new form of carrier for dark slides.

AUGUST 13th. Chairman, MR. FREDERICK YORK.—MR. W. M. AYRES showed a new dipper. MR. MORSE showed a new bath for developing dry plates. The CHAIRMAN then showed some comparative results of wet and dry plates, he giving the preference to wet plates for out-door work, and gelatine plates for interiors.

AUGUST 20th. Chairman, MR. P. MAWDSLEY.—Long and interesting discussion on the manipulation of gelatino-bromide plates by Messrs Warnerke, Payne Jennings, Foxlee, Bolton, Cowan, and Cobb.

AUGUST 27th. Chairman, MR. COBB.—MR. ALEXANDER COWAN explained an ingenious mechanical device for determining the diameter of stops to be used in lenses of different focal lengths the normal exposure of one stop being known, followed by discussion on intensification of gelatine plates.

SEPTEMBER 3rd. Chairman, MR. BOLAS, F.C.S.—MR. T. LANE exhibited a printing frame for double printing. MR. COLLINS suggested the desirability of collecting the portraits of notabilities in photography, past and present; Messrs. York, Cobb, Foxlee, and others giving their experiences in dry plate work.

SEPTEMBER 10th. MR. FOXLEE in the chair. MR. MAWDSLEY gave his experience in the variations of exposure which could be given to gelatine plates. Discussion on the relative merits of ferrous oxalate and pyro and ammonia as developers. Experimental exposures of gelatine plates, having reference to the granularity of the bromide of silver. Discussion on the comparative values of gelatine as sold by different manufacturers.

SEPTEMBER 17. MR. BOLTON in the chair.—The principal part of the evening was occupied in describing various samples of gelatine brought by Mr. Foxlee and Mr. Warnerke, followed by discussion on the stability of gelatine negatives.

SEPTEMBER 24. MR. DUNMORE in the chair.—MR. HENDERSON proposed the formation of a Club where photographers could meet weekly to discuss current topics, and where the nucleus of a reference library could be formed. MR. WARNERKE explained an arrangement for preserving ferrous oxalate developer. Prof. STEBBING described his method of intensification. Messrs. THOMPSON and EDWARDS also explained their methods.

At the conclusion of the report, Mr. Brittlebank proposed a number of names for election. MR. BOLTON also proposed some, and all being duly seconded and put to the meeting, the following gentlemen were elected:—Messrs. Raine, W. Bonner, C. Watkins, Talbot Lane, Tuhten, C. Tims, Harrison, C. Evans, G. Lee, Payne Jennings, G. Philips, Wheeler, A. King, Clark, Sutch, Collins, H. Wilmer, T. Peat, Lewin E. Morgan.

Professor STEBBING, from Paris, was then proposed and elected an honorary member of the Society, and in course of expressing his gratification and acceptance of the honour offered him, he suggested an interchange of portraits and pictures between this Society and the French Photographic Society.

MR. WILLIAM BROOKS said that some years ago he proposed to the Society a similar project.

After some further conversation it was agreed that an instruction be given to the Committee to take steps for furthering the project.

Further proceedings of a conversational character followed when

Mr. FOXLEE exhibited some examples of fading in common tinted papers, such as the *Globe* newspaper, which had lost their tint during a few hours' exposure to sunlight. This fading suggested the importance of care in adding tints to albumenized paper.

After some conversation, Mr. DUNMORE read a paper suggesting a scheme of competition photography similar to the competition sketching practised in sketching clubs. A subject was to be proposed each month by the President, and the competing students were to bring their photographs in illustration to the following monthly meeting (see p. 488.)

Mr. BLANCHARD thought the project a good one, but that one competition a year would be better than one every month. The latter was somewhat too much, and a little too ambitious.

The PRESIDENT also thought the idea a good one. He liked an ambitious aim, and quoted a modification of old Fuller's fine lines:

"Who aims the sky, shoots higher far
Than he who means a tree."

After some further conversation the proceedings terminated.

Talk in the Studio.

TREAT TO EMPLOYEES.—The employees, upwards of thirty, with Mr. W. H. Prestwich, of 155, City Road, were invited on Tuesday evening last to a spread to celebrate the birthday of their principal. The choir was taken by Mr. James Nesbitt, principal operator of the City Road establishment, the vice being the manager of the City house in Cheapside, Mr. R. S. Griffiths. After the toasts "The Queen," "The Army and Navy," "The Ladies" (coupled with the names of the Misses Nyns and Hortop), "The Visitors" (Messrs. Joh, Gunner, and Jex), the toast of the evening was given—"Our Employer, his Wife and Family," with three times three; to which Mr. Prestwich responded, thanking his people for their good wishes, also for their attention to business, and hoping that all would be with him for next year. After the "Chairman" and "Vice's" health, followed "The Greenwich," responded to by Mr. Bruycr, manager, and "The Cheapside," with Mr. Griffiths, the meeting broke up.

CHARGE AGAINST A PHOTOGRAPHER.—Yesterday, at the Windsor Petty Sessions, Mr. William Frederick Taylor, printer and stationer, High Street, Windsor, was charged with having unlawfully and feloniously delivered or caused to be delivered to M. J. H. M. Lacordaire, professor of the French language, at Twickenham, a certain paper, falsely purporting to be a process of the County Court of Berkshire, holden at Windsor on the 22nd of July last, knowing the same to be false. The document upon which the proceedings were founded was in the following terms:—"Preliminary Notice. County Court Summons. W. F. Taylor *versus* J. H. M. Lacordaire.—This is to give notice that on the 7th of August, 1879, you will have to appear at the Town Hall, Windsor, under a penalty of £10, to show cause why the amount of £2 6s. 1½d., owing to the said W. F. Taylor, is not duly paid. N.B.—This summons may be cancelled by mutual agreement, if the amount be paid to W. F. Taylor six clear days from the date of this summons." M. Lacordaire attended at the Windsor Town Hall on the day mentioned in the summons, when the Court was actually sitting, being anxious, as he said, to obey the law, and believing that he would be liable to a penalty of £10 for not attending. After waiting several hours, he spoke to the officer of the Court and produced the pretended summons, which was shown to the Judge, Mr. Whigham, Q.C., who ordered the document to be impounded. It was forwarded to the Treasury, and this prosecution was directed. In the course of the evidence it appeared that the claim was for photograph frames. Only a portion of the order, however, had been delivered, and this had been paid for. The magistrate committed Mr. Taylor for trial at the assizes, and admitted him to bail.

HUSNIK's plan for causing a chromated gelatine film to adhere to a zinc plate is to coat the zinc plate with a solution of three grammes of chromic acid in one thousand grammes of water; when the acid has acted upon the zinc, wash off the solution, and first coat the plate with plain gelatine, and then with the chromated gelatine. Treated in this way, the film is said to adhere very firmly to the zinc; but it must be kept dry before being used, otherwise a chemical reaction is apt to set in, by which the printing surface would be spotted.

To Correspondents.

R. E. WILKINSON.—The programme of the City and Guilds of London Institute Examinations, and other information, can be obtained of the Secretary to the Institute, Mercers Hall, E.C.

HUGH WALKER.—Your lens is what is termed plano-convex, but it is evidently not a photographic lens at all, and we do not see to what photographic purpose you can put it.

J. CLARK.—Gelatine negatives for printing a border or design round portraits may be obtained of Cussons and Co., Southport.

FRENCHMAN.—The wet collodion process as you work it will give the ordinary degree of rapidity. Whether the Boissonas process will give you greater rapidity we cannot say. It is impossible to speak of the time of exposure with any special lens in ordinary daylight, as daylight varies so much; exposure varies with time of day and with subject. There are gelatine plates much quicker than wet collodion. See examples in the Exhibition.

H. W. H. (Nottingham).—The subject of collodion transfers has been treated in various YEAR-BOOKS. It was fully treated in a recent number of the NEWS. There is no work devoted to the subject of enlargements generally. Orders for the YEAR-BOOK or NEWS you may require should be forwarded to the Publishers.

STAINER.—We have forwarded your letter.

B. L. F.—The term crystal varnish used to be applied to a clear white varnish for collodion positives. It was applied cold. So far as we know, it consisted of a solution of gum dammar in benzole. It was scarcely hard and protective enough for negatives. In the early days of photography it was often necessary for the photographer to make his own preparations; but at the present time he can purchase them better ready for use.

BEGINNER.—Anything which protects a photograph from atmospheric influences, damp, the products of burning gas, and foul air generally, will doubtless aid its permanency; hence enamelling will, there is little doubt, assist in securing permanency. For all small pictures it is, we think, an improvement. For large prints we prefer a matt surface; but if a glossy surface must be accepted, we think the enamelled surface preferable to the albumenized surface.

A SUFFERER complains of the injury to the eyes caused by continued use of the alkaline developer with ammonia. This is a trouble difficult to meet. With gelatine plates the forms of iron developer may be used, but many prefer the results of the alkaline pyro developer. It may be well to try a carbonated alkali, like carbonate of soda or potash. Both have been found successful by some, and either would remove the difficulty. Can you manage to secure a draught in your dark room which might carry the fumes of ammonia from you whilst developing?

REPRODUCTION.—The intensifier in which a little chloride of gold is added to a solution of mercury to which you refer gives very good results. The following is the best mode of using it:—Two stock solutions are kept: one consists of 1 grain chloride of gold to a drachm of water; and the other of 1 ounce bichloride of mercury and 1 ounce hydrochlorate ammonia to 20 ounces water. Two drachms of each solution should be added to 4 ounces of water, and applied to the negative, which has been developed with plain iron, fixed, and well washed.

A YOUNG AMATEUR.—You are right in supposing that special care should be used in packing photos. for transmission by post. They require such care, but rarely get it. Unmounted photographs are generally packed on deal rollers, and travel safely enough; but nine times out of ten they are inevitably injured in unpacking. The picture is rolled on first, and then the wrapping-paper is generally slipped an inch or two under the edge of the picture in commencing to roll round the wrapper. It follows that in tearing off the wrapper a portion of the picture is frequently torn as well, as the wrapper cannot be torn without tearing the picture, one edge of which is folded over it. When prints are packed in this way, it is, therefore, desirable to roll the prints round the wood first, and then place the wrapper completely over the print, without lifting up the edge of the latter to place wrapping-paper under it. In all cases avoid tying a piece of string tightly round such rolled prints, which leaves a line scarcely ever erased. Where it is desirable to secure the packet more perfectly than by a pasted wrapper, tie a piece of tape round each end of the roller. A better mode of packing unmounted prints consists in the use of a tube made of mill-board, or made by taking a sheet of brown paper, covering its surface with glue or paste, and rolling it round a wooden roller until a case of sufficient thickness be formed. Such a paper tube possesses sufficient rigidity to protect the print with greater lightness than the wood. The prints are not rolled on this tube, but rolled lightly up and slipped within it; they at once spring sufficiently open to fit the inside of the tube tightly, and a notch cut in each end and a string tied round, prevent risk of the prints either falling out or being abstracted, without infringing the conditions of the book-post.

RUSTICUS.—The Exhibition will remain open the whole of October and until the 13th of November from 10 a.m. till dusk, and on Monday and Saturday evenings from 7 till 10 p.m.

The Photographic News, October 17, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO

THE PRESS AND THE EXHIBITION—THE KING OF ZULU—LAND IN THE CAMERA—NEWSPAPER ILLUSTRATIONS BY PHOTOGRAPHY—FREE ADMISSIONS TO THE EXHIBITION.

The Press and the Exhibition.—It is difficult to be satisfied with the varied remarks with which the Photographic Exhibition is received by the press; but on the whole, no doubt, there is little to grumble about. On the contrary, if any feelings are aroused in the breasts of photographers who read the notices, they are humorous rather than critical. There is occasionally an innocent mixing up of processes—of confounding camera work with printing—which is, at times, decidedly funny, and we are always treated at the outset with a remark that a progress has now been made which a few years ago was never dreamt of—as if there had never been such things as Russell Manners Gordon's bijou landscapes nor Hubbard's cabinet pictures, nor such compositions as "Fading Away" and "Bringing Home the May," by H. P. Robinson. The hand that carried out Rejlander's famous studies has been still these three years, and it is quite as long since Mr. Earl, of Worcester, enchanted us with his grand sketches of Welsh scenery. We may still be progressing in our art, as we are gradually in the science of photography; but with such a past as we have seen we should certainly have dreamed of something better for the present, had we dreamed at all. One or two of our critics tell us further that permanency has at last been secured in photography by the platinotype process; but whether it is permanency in the negative or in the print, is not so clear. If the former, why then our negatives, we should say, have never had the fault of fading; and if prints are alluded to, there are some of us who have an idea that the difficulty was overcome when Mr. Swan showed his first carbon prints. We have no desire to speak otherwise than with commendation of the platinotype process of Mr. Willis, which is shown in the present exhibition to be capable of very varied application; but most of us have been familiar with the method for some time past, and know its characteristics, which are more welcome under some circumstances than they are in others. Whatever degree of permanency they may possess (and doubtless the platinotype prints are very durable), few unprejudiced photographers would rank them in this respect above or even on the same level as pigment prints prepared with Indian ink or other stable carbon compound. Again, on the subject of the gelatine pellicle, we see that emphasis is laid upon the simplicity of the gelatino-bromide. If the compound has a marked characteristic, it is rapidity; but whether regarded from the point of view of its preparation or development, one would hardly call gelatino-bromide simple as compared with other processes. As to the art criticisms expressed by the press, they are much too varied to pass an opinion upon; but, at any rate, we may congratulate ourselves that there is a disposition shown on the part of several of the papers to admit that photographers may sometimes be artists.

The King of Zululand in the Camera.—The account of the photographing of Cetewayo, with which we have been treated by the Cape papers, shows that the first portraits of the deposed monarch have been produced under rather difficult circumstances. He was, indeed, a brave man who attempted the work. The posing took place on board ship, the vessel rolling heavily, and a mild rain falling. Mr. Cetewayo was placed with his back against the binnacle, and, let us hope, with his head touching it also, if the ship were swaying to any extent. A double negative was taken, so that we may presume a rapid stereo camera was made use of for the purpose. But the difficulty with a dark skin is to secure half-tones. The bodies of our Zulu friends are apt, in photographs, to look exceedingly dark,

except as regards lips, nose, and ears, which usually shine so highly that they appear in a picture as if they were of burnished metal. To take satisfactory pictures of such models is, therefore, by no means an easy task; but we doubt not that an experienced photographer, after some practice, would be able to produce better work than that with which we have, so far, been treated from Zululand.

Newspaper Illustrations by Photography.—A new journal called *Life* is producing some fine photographic reproductions of paintings by a process termed phototypic. The prints are very finely executed, and of large size, and evidently printed in fatty ink. How they are produced we cannot say, for we have not, so far, had one of the impressions in our hands, or the opportunity of inspecting it narrowly; but that the impressions are not secured from a type block in a type printing press appears to us very evident. Of course there is no reason why the process by which it is produced should not be termed phototypic, only it is not what we, in this country, would understand by a phototype. We should rather say that the pictures we speak of are secured by a collographic method of some kind, of which, as everybody knows, there are endless varieties, both in this country and abroad. But however they are produced, the prints we have seen are exceptionally perfect, and we cannot help thinking that if the publishers can secure a wide choice of subjects to photograph, the prints will find ready purchasers among the public. The *Salon* will furnish every year a multiplicity of pictures, and when British artists see how well their brethren across the Channel become known and famous by this advertisement of their paintings, they, too, may grow wise, and open the Royal Academy for such work. Such copies of an artist's work so soon broadcast can only have the effect of enhancing the value of his original picture, and making his name more widely known, except, perhaps, in the few cases where the painting is engraved. But there are thousands of paintings exhibited every year in this country that are never reproduced by etching and engraving, and the copying and diffusion of these about the country by a process similar to that made use of by *Life* could only, in the end, be to the benefit of the artist. As to the profits arising out of such reproduction by photography, these might go to the artist just as well as to the publisher; and in the case of large editions being issued, the honorarium received by the artist ought to be a substantial one.

Free Admissions to the Exhibition.—The arrangement this year whereby one ticket is only available for one person at the Exhibition we regard as a very questionable improvement. At least it should be available for one friend, for it is rare, indeed, to find visitors going there by themselves, except in the case of casual passers-by, who pay for admittance, and are usually satisfied in half an hour or less. We suppose that the reason for the change is, that it is a simpler matter to keep tally when one person is admitted per ticket, and no doubt it is, but this is scarcely the only thing to be thought of. We have not yet arrived at that fortunate time when visitors will be so frequent that complimentary admissions will have to be cut down, and until that time arrives it is to the obvious good of the Society and the exhibitors that the collection should be as much visited as possible. When we can get people regularly to come in number to the annual exhibitions—and the general public are already learning that there is a photographic exhibition open every autumn—it will be time enough to restrict the issue of free admissions, and the step we have alluded to, practically does so now.

PHOTOGRAPHIC SIGNS OF THE TIMES.

BY WILLIAM COBB.*

It may be fairly inferred that our Society opens a fresh campaign under more than ordinary favourable circumstances, and, in addition to this, we may congratulate ourselves upon

* Read before the South London Photographic Society.

having a Secretary who has proved himself a technician of no mean order. The selection he has made for the reading of the first paper in this new session fully justifies this remark. You are all aware that hitherto a difficulty has always been experienced in inducing members to come forward with papers for reading at our usual monthly meetings. Now, in order to obviate this difficulty in the future, our Secretary has adopted the novel idea of selecting one of the least capable of performing that duty to come forward this evening in order to disperse anything like a feeling of diffidence, and also to inspire confidence in the minds of those who are far better qualified to occupy such a position. I sincerely hope that his little *ruse* may answer to his entire satisfaction, for it is very much to be regretted that the usefulness of a society of this kind—whose main object is, or ought to be, the dissemination of knowledge and the interchanging of ideas one with another—should be impeded from such an unworthy cause. For myself, I may say that I would willingly be regarded even as a scapegoat, if by that means the interests of the Society could be advanced in ever so slight a degree.

In casting about for a subject upon which to offer a few remarks to-night, I came to the conclusion that a few thoughts upon the "Photographic Signs of the Times" would not be altogether inappropriate, as it appears to me that they are just now very ominous.

It is often instructive—although, perhaps, at times somewhat humiliating—to take a retrospective view of ourselves and our doings. We can thus more easily detect our weak points, and so guard and fortify ourselves against a recurrence of errors into which we may have even unconsciously fallen.

This remark, I apprehend, is equally applicable to societies as to individuals, for we cannot close our eyes to the fact that the course of even photographic societies has not always run smoothly; and now that we see such unmistakable signs of renewed activity, increased energy, and a holder coming to the front, let us take care that our enthusiasm does not merge into recklessness, nor excess of zeal obscure our judgment. Profiting by past experience, and guided by discretion, we may be able to overcome all the difficulties which may stand in the way of our progress.

Photography has for some time past enjoyed a popularity such as no other science has ever risen to in such a short space of time. It embraces more within itself than any other branch in its universality; it occupies a position peculiarly its own; it has been made the exponent of many abstruse questions; and if its claims to be regarded as an art be ignored—although I believe it will eventually substantiate such claims—the sphere of usefulness which it commands is at least something to be proud of. I am, however, a little touchy upon this art question of photography, and so long as art exists only in emanations of imagination, pure and simple, without due regard to truth, so long will photography stand with a reproving frown on the borders of art's domain. But let it be once admitted that art may manifest itself in simple and refined truth, then may photography lift its dejected head and look forward with confidence to the time when its legitimate claims will be no longer ignored, but properly recognised and regarded.

Referring to the prostitution of art, hear what Ruskin said, now many years since: and I am inclined to think that things have not changed much for the better since that time. He says:—"The cause lies in the painter taking upon himself to modify God's work at his pleasure, casting the shadow of himself on all he sees, constituting himself artistic where it is honour to be a disciple, and exhibiting his ingenuity by the attainment of combinations whose highest praise is that they are impossible." Another art critic says:—"Those who are most capable of art are always most fond of nature, as such are chiefly sensible that all art consists in the imitation and study of nature. On the contrary, people of the common level of understanding are principally delighted with the little merits and fantastic operations of art, and constantly think that finest which is least natural."

But, after all, photographers have themselves much to

blame for the withering remarks which have from time to time been levelled at them and their profession. True it is that their ranks have been greatly augmented by those whose only ambition was to secure the "pot boilers" in photography, and not actuated in the least degree by a desire to raise it to its proper level. It is, however, a healthy sign of the times that these are being gradually weeded out, and a corresponding improvement in the quality of photographic work generally is also greatly discernible.

Those of us who may be regarded as having borne the heat and burden of the day, in a photographic sense, can hardly fail to recognise the great advantage which must arise from the improved method of working which has so recently been introduced, and now becoming so popular in our studios. Upon the young especially who have adopted photography as a profession would I urge the necessity of close application and study, for there is still a very wide field of research open to them which will well repay their diligence. I am well aware that it is not for all to become leaders in their profession, for there must be the "brewers of wood," &c.; and, although it may be that—

"There's a divinity that shapes our ends,
Rough-hew them how we will,"

it is, nevertheless, a fact that every man is to an extent the architect of his own fortune and position in life.

A considerable amount of correspondence has taken place both with regard to operators and assistants, and I cannot help thinking that there is far too much reason in the complaints which have been made in reference to that class. There seems to me to be a want of enthusiasm, or what our American cousins very aptly call "go." Now I can hardly imagine a really first-class photographer who lacks enthusiasm. The cold, half-hearted, phlegmatic individual altogether mistakes his vocation when he identifies himself with photography by way of making it his profession, and will ultimately regret having done so.

I cannot allow this occasion to pass without referring to the very pleasant meetings which have been held during the recess. I am sure the thanks of this Society are due to our friend, Mr. A. Brittlebank, for his great kindness in throwing open his rooms, and so giving us the opportunity of meeting for the purpose of discussing various subjects of interest in connection with our art. The manner in which these meetings have been conducted reflects great credit alike on Mr. Brittlebank and the members who have availed themselves of the means thus provided for their benefit. One effect of these meetings has been to prove the existence of a want which, through the liberality of a gentleman well known to most of us, is in a fair way of being supplied. Mr. A. L. Henderson has very generously come forward with a donation of one hundred guineas, provided a similar sum can be raised by the rest of our members or others who may feel interested in the scheme, with the object of founding a photographic club. The full particulars of the movement will be duly announced, and it is to be sincerely hoped that all the members of this Society will show their appreciation of Mr. Henderson's hearty good will by giving their support and co-operation in connection with such a laudable enterprise.

I will no longer trespass upon your time, as I know you are all anxious to hear any remarks which our good friend, Mr. Brittlebank, has to bring before us.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER VII.

MORE CHANGES—PHOTOGRAPHING CHILDREN—"CAN'T YOU FIND SUMMAT TO DO?"

SUCH men as Russet never thrive—never succeed! The public has a keen eye to the fixings of a place, and can tell *instantly* whether a nail has been driven by an amateur or a professional; besides, they object to seeing sawdust and nails being hurriedly swept up on their appear-

ance; it breeds a certain distrust in their minds, and, in consequence, they are almost sure to grumble at their pictures. So Russet, in spite of his hammers and saws and teetotalism, went to the bad.

My next employer was a character of another sort. He seemed imbued with the idea that the sole aim of photography should be to immortalize children. "You are no use to me," he exclaimed at our first interview, "unless you are successful with children! You please the children, and you can get what mouey you like out of the parents. Look round you, and you will see how I manage it." And a capital way he did manage it, but one that I found rather hindered the business, and interfered with my comfort during the term I served him.

This place of business was a veritable Noah's ark—a Wombwell's menagerie on a small scale. Everything was there that could amuse, astonish, or alarm the infant mind. In the passage you found a fountain, globes with gold fish, and a tank of sea water containing winkles, limpets, crabs, crawfish, and other crustacea; further along you entered a room flourishing with flowers, and musical (?) with birds. There were parrots with flippant talk, magpies with shrill chatter, rooks with solemn caws, canaries, larks, love birds, and heaven knows what besides. This room opened on one side to a garden, surrounded by cages containing rabbits, guinea pigs, fowls, pigeons, &c., and in a huge dog box was a chained fox. The studio and reception rooms were lumbered with rocking-horses and dolls. So far, all this was good, and Hamilton gained great fame among married folks. Fond mothers would bring their dear urchins for miles by the train to have them photographed by Hamilton. The place very often resembled a show, and what awful jobs I had sometimes to get the little beggars to quit the birds or animals, and sit quiet for two or three seconds! Mama wished dear Tommy and little Annie taken together; she was sure it would make such a lovely picture! Little Annie was feeding the pretty Poll, and dear Tommy was hugging the old fox. Mama went to fetch Tommy, and nurse made a raid upon Annie when I informed them that I was ready. Screams—shouts—rebellion! Then enter my two subjects howling. Little Annie wanted the dear old Poll, and Master Tommy sulkily demanded the fox. And poor Geo' had to make a pretty picture of them!

As a rule, I am not given to the use of strong or profane language, but I am afraid I shall have to account for a large amount of vile adjectives made use of during my stay with Hamilton. However, I did not forget Ballarat's advice, taking good care to let the steam come off only when I was in the dark room. I had such a hatred at the animal world at that time that I could scarcely be induced to pass a dog in the street without kicking it; and had you shown me a "Goldsmith's Animated Nature" I would have had your blood.

But my greatest trouble centred itself on two monkeys—two great, grey, mischievous brutes from the wilds of Gibraltar. The ill-conditioned brutes were chained to perches one on each side of the passage that led to the glass room, and very often, as I ushered some sinner into the room, my head would come within easy reach of one of them, and I would instantly lose a handful of hair. Now I am sharp enough at seeing fun, and generally know pretty well where the laugh comes in, but to this moment I fail to see what fun there was in that; yet when I complained to Hamilton, he held his sides and roared as if it was the best joke he had ever heard.

I dare say the reader will not be amazed to learn that Hamilton, like Russet, failed to make money. The birds, and the animals, and the toys were all a mistake. The pictures, although sharp and well exposed, were generally lacking in expression; it was rarely that ever a child entered that glass room with a pleasant face, and during his stay he was restless and impatient to get out to the monkeys or other brutes. "Many men, many minds," as

the saying is; but I cannot help saying once more that toys in the glass room is a mistake—a great mistake. I am now very successful with children, and I have no trouble with them. My plan is simple, but effective. If possible, I take all my children by appointment; when they arrive they are shown to the dressing room, where mama or nurse makes the darlings ready. I go to my dark room, prepare my plate, arrange my blinds and lighting, and, in short, have everything ready when my little visitor arrives. Quickly, but without bustle, the pose is got, the focus obtained, and then I speak for the first time. The child's attention is immediately rivetted, the cap withdrawn, and one—two—three—four—speaking all the time—the picture is taken. All the attraction I have in the shape of toys or noise is a little bell which I use for the very young babies.

As you may suppose, I did not stay long with Hamilton. I wouldn't have had a hair between me and heaven if I had stayed long. At this period I visited London for the first time, but although well recommended and good character, I failed to get a situation in a good house; things were very backward that year, and I found the employers turning away their assistants in place of engaging more.

I was not very much depressed—I was single then, and had saved some money, so I walked about and enjoyed to the full the sights of London. I had walked from Paddington to Mile End, from "Mother Red Cap" to the "Elephant and Castle," and was on the point of turning my nose northward again, when, by accident, I dropped upon a wonderful and exceptional sample of the photographic profession.

This studio stood in an out-of-the-way corner in rather a stirring neighbourhood; the front of his building was plastered over with bills and show-cases; conspicuous among the last was a case containing letters from bishops, lords, and grand people, praising his work and giving immense orders. It reminded me of the flaming notices outside the booths at country fairs: "Patronized by all the crowned heads in Europe." In gilt letters over his show-cases flamed the striking name of "Baron Bilklarsky, Artist."

By Jove! Here was a foreign nobleman, I thought; I hope he is in want of some one; and I entered the shop, to find myself face to face with the noble baron. I confess I was somewhat disappointed at his insignificant appearance. He was black, little, and white-faced. However, he treated me civil enough, and listened to me patiently. He shook his head despondingly when I finished, and cried, "Bad times!—bad times! but hi 'ave reasons to be thankful! Hi 'ave room for you, but I can't give you much mouey. 'Owever, you knows as 'ow 'arf a loaf is better than none, and if you likes you can come to-morrow morning."

I was profuse in my thanks, and there and then engaged to the noble Barou at a mere nominal figure. I can't help laughing now when I remember the sweating process that the noble Baron put me through during the few days I remained with him. He was an artful cad, and took advantage of the countryman. He started me to clean up his place—Heaven knows when it had been touched in that way—and I scrubbed, and brushed, and coughed, and sneezed, and carried forth bucket after bucket of filth until I was as tired as I possibly could be, and as black as a sweep. When I sat down to have a moment's rest he pounced upon me. "What!" he cried, "can't you find summat to do?" and then he would start me off upon another brushing and scrubbing expedition. On the evening of the second day, just as it was getting dusk, and while I, dirty, sticky, and tired, rested my back against the door of the dark-room, up jumps the Baron, like a Jack-in-the-box, shouting his favorite war cry, "Can't you find summat to do?"

I told him I thought I had done pretty well for one day. He lifted up his hands in amazement, and pointing to the

glass room windows exclaimed, "I declare, you 'ave not touched these winders, and I expressly told you to! Here are the leathers—stick into them!"

"Baron Bilklarsky!" I exclaimed with dignity, "is it customary for your operators to clean your windows?"

"Certainly—certainly; people must not be above their work!" and he grinned wickedly as he spoke. I said nothing in reply, but went out and engaged a lad to clean them, paying him a shilling for the job. The Baron said nothing, but chuckled and grinned in the most provoking manner, while I walked about in dignified silence and watched the lad. At length the job was done, and I prepared to go. I deliberated whether I should not have an understanding with him at once or not: when, recollecting that the cleaning was all done now, and I possibly might have a quieter life of it in future, I resolved to depart in peace, when lo! at the foot of the stairs I stumbled upon a gas collector.

"William Clark?" he exclaimed, inquiringly.

"No one of that name here," I answered. "Baron Bilklarsky is the only tenant here."

"Bosh! He's no more a Baron than I am!" cried the collector, evidently getting angry. "I know him! His name's here—William Clark—and him and I was at school together; and what's more, if he don't pay his gas to-night I'll turn it off at the main!"

"Wait a minute; I'll tell him you are here!" I cried, seized with a sudden idea. I then bounded up the stairs, and opening the door, shouted, "Mr. William Clark, here is the gas collector come for his money, and if you don't pay he'll turn it off at the main!"

I shall never forget his face at that moment! The grin was all on my side now. He seized a broom, and showing his teeth like a baboon that meant business, he came towards me in such a manner that I deemed it prudent to depart without further parley.

As I said before, he was an artful cad. He got the countryman to clean his place and pay a man to clean his windows—and all for nothing.

(To be continued).

PHOTO-MECHANICAL PRINTING AMONG THE JAPANESE.

IN the course of one of my peregrinations in the streets of Tokio—writes Baron R. von Stillfried* to the *Photographische Correspondenz*—I was struck with the appearance of a print in a printseller's shop, and my curiosity was excited to the highest degree when the owner of the establishment assured me that the print in question had been produced by the aid of photography, and by a new method—the invention of a Japanese. The result of this was, that after some trouble I found out the inventor, but I cannot pretend to have been received by him with any degree of civility. Such a reception, however, was only to be expected by one who is acquainted with the love of the Japanese for mystery, and their mistrust for foreigners. The man was exceedingly uncommunicative, returned no answers to my questions, and would not hear of selling me his secret. I was, therefore, half inclined to give the matter up, especially as I was very busy in other quarters, and after examining the proofs had no very great opinion of the process itself. Chance, however, threw in my way a young man who, as it subsequently appeared, was an opponent of the inventor's, and from him I learned some particulars which seem to be worth noting, and which, after I have followed them up, I hope to be able to report with greater detail and certainty.

Meanwhile I have ascertained what follows. There appears to be a certain substance, sensitive to light, which has long been known to the lacquer manufacturer. This substance is said to be of a brown red colour, and of the

consistency of putty; it possesses the property of becoming hard under the action of light, and, if dissolved in certain solvents, which are unknown to me, it is deposited therefrom, but when kept in the dark it remains soft and soluble. A plane wooden block is coated with this pasty substance to a thickness of about five millim., and the whole made smooth with a roller; it is then exposed under a negative. After exposure for about twelve hours in the sunlight the image will be seen to be transferred to the block, in that the exposed parts have not only become hard as stone, but have also lost the peculiar lustre possessed by the soft mass; hence a dull map is seen on a glossy ground. Now, if I have rightly understood my informant, the highest lights are then removed with a scraper made of bamboo, a process which appears to be very easy, as the outlines of the exposed parts are so very hard as to render an encroachment on them impossible. With another instrument, shaped like a comb, and also made of bamboo, the parts to remain white are then worked up by passing the instrument into and across them, and the whole is finally exposed again to the light, so as to render hard the still soft parts. The plate, which I had an opportunity of examining, although prepared in this rough and primitive fashion, appeared to have quite sufficient depth for printing purposes. Apart from the fact that the process seems ill adapted for the reproduction of half-tones, even with the above-mentioned after-working, the defects of this plate seem to be due to the unskilfulness of the workman in the use of the bamboo comb, and to the fact that the negative itself was a bad reproduction of an equally bad photograph. With negatives of linear drawings, the parts that remain soft and soluble are said to be removed by the application of a solvent, and the plate is then ready for printing without a second exposure.

In the plate to which I had access, and in examining which I was watched with Argus eyes, I was able to see that the depth (about three millim.) was quite sufficient, and also to note the thickness of the layer on the wood-block. Of the colour and other qualities of the substance I could form no opinion, because it was completely blackened with the ink, and I was not allowed to do anything to the plate. Taking advantage, however, of a lucky moment when I was unobserved, I succeeded in proving that the substance is as hard as stone, for it resisted an attempt to cut into it with a knife. In the plate to which I refer, which was the reproduction of a figure, nothing except the white of the shirt had been taken out; the lights of the face seemed to have been pressed in with a blunt instrument. The paring and scraping to which the parts representing the dress and background had been subjected were quite visible, notwithstanding the thick layer of ink. The printing is carried out in the same way as the Japanese wood printing, which has often been described; Chinese ink is used, and the absorptive quality of the Japanese paper is of great importance.

My informant, who had only seen the process in execution, and otherwise understood nothing of printing, promised to get me further information, and to obtain some specimens of the substance before it had been acted on by light. I showed him some asphalt and some bichromate of potassium, but he assured me that nothing resembling either of these was used in the process, or he would have been sure to have seen it. Still, I hope to get at the bottom of the subject, though this is not so easy in Japan. I should be very glad to receive from technical photographers any hints or advice on my future researches, and any surmises as to the nature of the substance.

PHOTOGRAPHING CETEWAYO.

A SOUTH AFRICAN journal, the *Cape Times*, gives some details of the bearing of the great Zulu chief in front of the camera. After describing his experiences on board ship, the reporter says:—

He has not given over the assertion of his dignity; and

* Professor of Photography and the Director of the Photographic Department of the Imperial State Printing Office in Tokio.

in this, I think, he has been much encouraged by the amount of waiting upon which he has received. On Saturday last, after promising to have his photograph taken, he kept photographer and every one else waiting upon his pleasure for some hours. He was pleased to be gracious enough for a few minutes, and then went back doggedly to his seclusion. His observations often show, as his face would convey, that he possesses no inconsiderable fund of humour. He was good enough to come out of his shell during the time his photograph was being taken, and the smiling face he put on, as his photograph will show, proves that he is not altogether unacquainted with the ways of the world. When his wives were being photographed, nothing could induce them to leave off giggling or to sit still, until Cetewayo sternly commanded them to do so; and then at once they were as motionless as statues—it was evident they had not forgotten the temper of the king, and the way he once reigned in Zululand. When he was afterwards asked to sit for another photograph he declined doing so, on the ground that he was not going to make a fool of himself twice in one day. He would not sit with his wives, because, he said, having his photograph, they could easily cut the group of women in two, to put him in the centre; and he suggested that if other photographers wanted his likeness they could photograph his followers as often as they liked, and the pictures would sell just as well; for the white man would buy anything. The photograph will show Cetewayo to be an enormous man of a little under six feet high, a handsome, over-fed specimen of humanity, with nothing repulsive whatever about him. A tape measure round the chest would probably show sixty inches, and each thigh half that number of inches; and this should convey what an immense fellow the king is. Yet he is not ungainly in figure, and there is an unmistakable dignity about him, which, together with his fits of sociability, have drawn towards him the good feelings of his escort.

The wives of the king, who are his fellow captives, are four in number, and are tall, lithe, shapely women of about twenty years of age. The photographs are not just to them, for their attractions seem to be in their vivacity and their good temper. Like their lord and master, they are anxious about their dress, and at the present rate of 'petting' to which they are indulged we may expect before long to hear of their subscribing to the *Ladies Journal*. On Sunday Cetewayo was taken on a tour of inspection of Her Majesty's ship *Boadicea*, which visit seems to have given him a terrible shock; such a visit a year ago might have saved England some millions of money."

The photographer who "took" Cetewayo on board the *Natal* says:—

"On Saturday morning the steamer was rolling too much to be sure of success. We, however, were obliged to do the best possible under the circumstances. Having placed everything in readiness, we informed the king, through his interpreter, that we were ready, and received answer that the king was 'going to sleep,' and did not wish to be disturbed. After a while we could hear him speak, so we once more informed him that we were waiting for him. He did not seem inclined to appear, and Captain Poole thought it best to give him some inducement to do so, which was accomplished by catching a fish. This made him come out at once, and after some palaver the king was persuaded to seat himself near the compass, with his back against the wheel. He appeared to be very nervous, and requested that it might be done at once in order to have it over. He seemed to dread the camera, and did not like the look of the lens. We succeeded, however, in getting our first double negative. He was more at ease when he found that it was done without his being hurt; but in order to show him what we were doing, Commander Caffyn showed him a photo of Dabulamanzi, at which he seemed pleased, and at once disencumbered himself of his blanket to show his figure, of which he appears to be very proud. We succeeded in a second double negative, and then he sternly refused to have any more taken."

THE PRESS AND THE EXHIBITION.

(From the *ECHO*.)

THE annual exhibition of the Photographic Society, which was opened at the Gallery of the Old Water-Colour Society, Pall Mall East, yesterday, possesses an unusual degree of interest, not only for members of the profession and amateurs, but for the public at large. Both from a scientific and an

artistic point of view, the feature of the present collection which most particularly deserves and commands attention, consists of the admirable examples it comprises of portraits, landscapes, and seascapes painted from negatives taken instantaneously on gelatine plates. Experiments with this process have only been carried on for a little over two years, but it would already seem to be almost perfected, a result which is generally ascribed to the labours of an amateur named Mr. C. Bonnett. The fact that a photograph can be taken by the gelatine process in a sixth of the time, during summer, that would be required if the collodion process were employed, and in a twentieth part of the time during the winter season, gives it an obvious and extraordinary advantage over its rival. People will, practically, no longer have to "sit for their portraits," which, in the majority of cases, involves the assumption of an unnatural and uncharacteristic expression of countenance and pose of figure, and which has been the cause of some of the most marked and vulgar defects of photographic portraiture. In photographing landscape, the life, movement, and sentiment of Nature will be preserved by the new process in a measure that the old one, which it threatens to supersede, never attained. All that is most beautiful in man and Nature is fleeting, and subtle, and delicate, and no chemical process that is not instantaneous can ever hope effectively to render, even in black and white, the momentary and evanescent. The pulsations of light and shade in the air, their gleam and play on stagnant or rippling water, the procession of the clouds in the sky—now rushing broken and wild in an upper current of wind, and now reposing in majestic, rock-like firmness on the deep, still azure spaces—these are aspects of external nature that photographers have never yet been able to portray with any close approximation to the realities, and there are corresponding traits of human character and grace that have equally eluded their grasp. It would, perhaps, be too much to say that photography has at last, so far as form is concerned, come into threatening competition with *Fine Art* in any of its divisions, but it has certainly advanced a considerable way in that direction, and promises to progress still further. Let anyone examine Mr. Joseph Gale's two small photographs of "Brixham Trawlers" setting out to sea (Nos. 4 and 5), and the same artistic amateur's "Landscape" (No. 7), where the swallow is swiftly flashing over a lake that reflects her shadow on its clear bosom—all of which are taken from instantaneous gelatine plates—and he will have a very favourable opinion of the capabilities of the new process. Messrs. Wratten and Waiuwright's "Instantaneous Views of the Boat-race, 1879" (No. 373), with the bustling river and puffing smoke, are also capital examples of this method. In the department of portraiture there are no works in this exhibition that excel, or perhaps equal, Mr. Robert Faulkner's "Portraits of Princess Victoria, Princess Maud, and Princess Louisa of Wales" (113), and his "Three Studies of Expression" (114), enlarged cartoons worked up in red carbon; but the "Specimens of Portraiture taken on Gelatine Plates" (129), which hang near, are little inferior to them. Attention will also be attracted to the clever specimens of Negatives printed in Platinotype (311 to 351) by the inventor of that new process, Mr. W. Willis, jun., of Leo. These works are permanent, and have many attractions, notwithstanding a certain coldness and hardness of tone. It would be impossible for us to mention the whole of the large proportion of the 404 entries in the catalogue of this exhibition that we have marked for commendation. Mr. Vernon Heath's "Burnham Beeches" (7), "A Group of Firs," an untouched enlargement (14), and other contributions from the School of Military Engineering; Mr. S. G. Payne's agricultural scenes, so solid and substantial (ranging from 64 to 71); Mr. Payne Jenning's landscapes, taken both by the old and new process (from 176 to 184); Col. H. Stuart Wortley's admirable studies of breaking waves and moving clouds (from 187 to 204); Mr. H. Garrett Cocking's melodramatically-composed, but well-executed "Fern Seller" (223); and enlarged portraits of Professor Huxley (242) and Mr. Birket-Foster (267), by the Woodbury Company—are, however, works of very conspicuous merit. A similar compliment must also be paid to the highly-picturesque portraits of "Inhabitants of Armenia," and pictures of "Incidents of the War, 1877-8" (383), taken by a native photographer named Nikitin, and to Mr. F. G. Newton's "Views in Demerara, taken on a visit on the Falls of Kaieteur" (386). Altogether there is much to interest and instruct the public in the present exhibition of the Photographic Society.

THE PHOTOGRAPHIC EXHIBITION.

CLOSER inspection and more close familiarity do not in any degree militate against our high appreciation of the general excellence and highly interesting character of the present Exhibition. Of absolute novelty there is very little. There are no great pictures, no very ambitious attempts. In photo-engraving, a direction in which we naturally look for progress, there is nothing new. There are not even any new styles in portraiture. No new carbon or other printing process. But there is a high general excellency, whilst in art qualities there are a few pictures as much above the general excellence as a few years ago there were a few above the general mediocrity. In the growth of photography, as in the advance of civilization generally, the progress is lateral as much as upward. Of those who take the last few steps from high excellence to perfection, the number is always small.

It is remarkable that of those pictures which possess distinguishing excellence the majority are produced by the aid of gelatine plates. We say the majority, because it is not the case with all. The five instantaneous studies of English rural life by S. G. Payne are produced by wet collodion, that gentleman, as he assures us, never having succeeded so well with gelatine as with wet collodion, although his gelatine results, as evidenced in some groups of children before us, are very excellent. Some of Colonel Wortley's grand instantaneous effects are also by wet collodion. The superb landscapes exhibited by Mr. W. Bedford are all, we believe, from wet collodion negatives.

Gelatine plates do, on the whole, however, take first rank in excellence, or excel in those special qualities wherein hitherto dry plates are supposed to be wanting. The little gems exhibited by Mr. Joseph Gale, "Brixham Trawlers," are fine examples of all which dry plates were once supposed to be incapable of giving, singular delicacy and softness. Their artistic qualities are the charm of the pictures, but these artistic characteristics owe much to precisely the right technical qualities. The composition of the group of boats in each is very admirable; but if the development had been less judicious, if it had been managed so as to produce hard black-and-white results, all pictorial charm would have vanished. As it is, there is a soft transparency and tenderness which is very valuable: a white sky and white sea would have spoiled all pictorial effect. A pretty bit of landscape (No. 6) is rather black, but possesses an especial interest in a well-made out swallow flying low and skimming the surface of a piece of water, in which it is well reflected. The lines appended are appropriate—

"The swallow, too, is come at last,

I saw her dash with rapid wing,
And hailed her as she passed."

The effect here is perfectly satisfactory, and question as to the genuineness of the result, and whether bird and landscape were produced at once in one negative, or whether the result is due to skilled combination, is scarcely fair. If due to the latter, we can only say it is most skilfully effected; and if the result of one shot, the skill and the good luck are both exceptional.
